APPLES, 37½ Cents. Pyrus *malus.*

Class, *Icosandria.* Order, *Pentagynia.*

[In the arrangement of the Apples, I have thought best to place those which are peculiarly adapted for Cider in a separate division—there is but little doubt, however, that many of those kinds now more particularly esteemed for the Table, may, on trial, prove extremely good for Cider also. Where such trials have already proved successful, it is designated. I have also designated those which have originated in America with an asterisk.]

TABLE FRUIT.

C denotes those which have proved good for Cider also.
P ——— those which are also proper for preserving or cooking.
* ——— native American fruits.

1	*YELLOW harvest, *fit for tarts, and an excellent table fruit*	*ripe in* July.

GOOSEBERRIES. Ribes *Uva-crispa.*

Class, *Pentandria.* Order, *Monogynia.*

Different kinds by name, 31¼ *cts.*
Do. do. mixed, 25 *cts.*

[Of this fruit several hundred varieties have been imported from England, where they excel in its cultivation, especially in Lancashire and Yorkshire; and where they frequently weigh from one to one and a quarter ounces. The following have been selected on account of their large size, flavour, or time of ripening; and many of them have, in turns, obtained the premiums at the annual exhibitions in England. But *to have this fruit succeed well*, attention must be paid to the *directions* attached to this catalogue.]

HOP ROOTS *per hundred*, $5.

GRAPES. Vitis *vinifera*.

Class, *Pentandria*. Order, *Monogynia*.

37½ Cents, except those noted.

The foreign Grapes included in the following assortment, are reared from plants imported *direct* from the most celebrated collections in France, Germany, and the Crimea, many of which contain from four to five hundred varieties, and descriptions of nearly all of them will be found in the most celebrated works on the culture of the Vine—such as Chaptal, Bon Jardinier, Duhammel, Speechley, Forsyth, &c.—and also in the Treatise attached to this Catalogue. Many of them will be found to differ essentially from fruits cultivated under similar names in some parts of the United States, as in many instances the possessors of Grapes of doubtful origin have attached to them the names of old established fruits. This practice, so common in our country, and so calculated to disseminate error, cannot be too greatly deprecated. I have also to acknowledge the recent reception of some valuable German Grapes from that distinguished philanthropist, Col. George Gibbs, of Sunswick, Long-Island, which were received by him direct from the Government Botanic Garden of Austria, and which are inserted in this catalogue.—So confident has the proprietor ever been of the success which would attend the culture of the Vine in this country, and of the utter inconsistency of the fallacious ideas which have been advanced to the contrary, that he has *extended* his collection of Vines by importations of the *choicest kinds* from every clime; and as he has, during the present season, had near 100 kinds to produce fruit equal to that of France, nearly all of which ripened in August, he considers these doubts as entirely set at rest.—*Specimen Vines*, of every kind, have been planted out for bearing, and persons desirous of seeing the fruit, can view them at the season of ripening.—Such persons as desire a selection of varieties most suitable to their particular localities, can have the selection made by the proprietor.

C denotes those which ripen well in the city only in this latitude.
C C ——— those which ripen well both in city and country.
* ——— celebrated wine grapes.

1	July grape, *early black cluster, précoce de la madeleine*, or *morillon hatif*, C C	*r. begin. of*	Aug.

ROSES. Rosa.

Class, *Icosandria.* Order, *Polygynia.*

This favourite flower has been cultivated to such an extent in Europe that it combines almost every tint of which nature is susceptible, and some of their collections contain above 1400 superb varieties. The following have been selected on account of their fragrance, size, beauty, singularity, or delicacy, and the original plants of many of these kinds cost from $1 60 cents to $4 75 cents each, exclusive of the expenses and losses attending importation. The collection *occupies an acre of ground,* where all the kinds are marked with their respective names, and during the period of their bloom they present an accumulation of varied beauties scarcely to be rivalled, and those who may desire it can make their selections when in flower.—All the following Roses will endure the winters of any part of the Union without protection, except the *white musk,* which should be covered with some straw, &c. during winter.

* denotes those that are 25 cents.
† ——— 37½ cents.
‡ ——— 50 cents.
¶ ——— 75 cents.

* So called in London, in honour of Miss Lawrence of that city, authoress of a splendid work on this delightful class of plants.

PÆONIES. Class, *Polyandria.* Order, *Digynia.*

[No class of flowers has recently attracted more attention in Europe than this, a monograph of which has recently been published in London. Most of the varieties are extremely splendid, and others possess striking peculiarities. Anticipating that a similar taste would be evinced in this country, the proprietor has, by great exertion, obtained every variety yet known to exist.]

CHINESE CHRYSANTHEMUMS.

Chrysanthemum *indicum*.

Class, *Syngenesia*. Order, *Superflua*.

50 cents, except those noted.

[This superb flower (vulgarly denominated Artemesia) is deservedly esteemed; being perfectly hardy, and affording a most brilliant display, at a time when the chilling blasts of autumn have left us but the vestiges of departed verdure. It is therefore a subject of much gratification, that the number known to be cultivated in China exceeds 50 varieties, nearly the whole of which will be offered to the public in the next catalogue.]

13	Cortusa-leaved, 1 dollar	cortusoides

IRIS, or *Fleur-de Louis.* 25 Cents, except those noted.

Class, *Triandria.* Order, *Monogynia.*

[This flower, from its great combination of colours, (whence it derives its name,) and altogether unique appearance, has ever found admirers among the curious and the scientific. By the recent addition of a large division of the genus *Morœa*, the number of species has been increased to 70; to which may be added about 30 splendid varieties, which have been raised from seed by the Dutch. Arrangements have been made to import nearly all the other *hardy* species, which will be received in the autumn of the present year.]

78	Common winter cherry	Physalis alkekengi
79	Anise	Pimpinella anisum
80	Swamp cabbage	Pothos fœtida
81	Common burnet	Poterium sanguisorba

BULBOUS

AND

TUBEROUS ROOTED PLANTS.

The following have been selected with great care from the finest collections in Europe, and are remarkable for their size, beauty, or delicacy; they are cultivated under the same names by which they were imported, and the prices of many of them are less than the retail prices in Holland, the proprietor relying on the increase for remuneration. In the selection no expence has been spared, and the choicest flowers have been culled from the finest collections of Holland and Flanders—more on account of this being a favourite class of plants with the proprietor, than from any expectation of profit. It can, therefore, with the utmost confidence, be asserted, that the collection now offered to the public, the first cost of which was near four thousand dollars, is not surpassed in those intrinsic qualities, which constitute the peculiar charms of this class of plants, by any other in the world.

‡ denotes extra fine sorts.
† ——— the earliest sorts.
* ——— those that are tender.

N. B. Where the prices are by the dozen, the selection must be left to the proprietor.

DOUBLE HYACINTHS.

51 Yellow do.	flava	50
52 Large flowering do.	grandiflora	50

N. B. For other choice Bulbs, see Green-House Plants—such as Ixias, Pancratiums, Crinums, Oxalis, Feraria, Hæmanthus, Cyclamens, Antholyzas, Eucomis, Veltheimia, also Dahlias, &c. &c.

GREEN-HOUSE TREES, SHRUBS, AND PLANTS.

Nearly all of which thrive in a comfortable sitting-room during the winter—they are in either pots or boxes, and the prices are inclusive. It will be perceived that immense acquisitions have been made to the Green-House department, and great perspicuity and attention have been bestowed in order to select the most beautiful and interesting—the collection will also be found extremely rich in Chinese and Japan plants. Those which have no prices attached to them will not be for sale until the autumn of 1825.

N. B. These checked thus * though generally cultivated as Green-House Plants, will stand the winters of the Middle States in the open air, and a very large proportion of the others will support the winters of the Southern States.

		Each. $ cts.
1 Maple leaved abroma	Abroma augustum	2
2 Prickly leaved acacia	Acacia armata	1

A SHORT TREATISE

On the Management of Fruit and Ornamental Trees, Shrubs, Plants, &c. with cursory Descriptions of some which are of recent introduction and acknowledged merit.

THE Proprietor of the LINNÆAN GARDEN, in supplying the orders for Trees, &c. from remote parts of the United States, having frequent applications for directions for their management to accompany them, concludes that the following brief remarks will be found acceptable.

Season for Transplanting.

Spring is the season when we find the most pleasure in making our rural improvements, and from this circumstance probably it has become the most general season for planting trees—but experience has proved the fall planting to be the most successful, especially in those parts of the United States which are subject to droughts, as the trees planted in autumn suffer little or none from a drought, when those set out in spring often perish in consequence of it.

Trees, &c. on their arrival at the place of destination.

As soon as the trees arrive at the place where they are to be planted, let a trench be dug in cultivated ground, the bundles unpacked, and the roots well wet and immediately covered with earth in the trench, observing to make the earth fine that is spread over them, so as not to leave vacancies for the admission of air to dry the roots—it having been found by experience, that the thriftiness of trees, the first season after transplantation, depends much on the fine fibres of the roots being kept moist, and not suffered to dry from the time they are taken up until they are replanted—a precaution which is always attended to with respect to the trees sent from this garden, as the roots are invariably kept moist from the time they are taken up until they are packed ready to be shipped. Their success, therefore, must depend principally on the subsequent management on their arrival at the place of destination; for if, when the bundles are unpacked, the trees are carelessly left exposed to drying winds, the young

fibres of the roots must perish, and the trees, if they live at all, cannot thrive the first season, as they can receive little or no nourishment until those fibres are replaced.

Manner of Planting.

Let the holes be dug somewhat larger than is sufficient to admit the roots in their natural position, and of sufficient depth to allow the tree to be placed two or three inches deeper than it was before transplanting—take care to cut off any wounded parts of the root, and to reduce the top full one third, by shortening the branches or thinning them out. Let from two to four shovelfuls of well rotted stable manure, in proportion to the size of the tree, be incorporated with the earth, and the whole made fine previous to filling it in; and, during the operation of filling in the earth, let the tree be several times shaken, in order that the soil may be admitted among the finer roots, and when completely filled up, let the ground be well trodden down, and finish by making a hollow or basin around the tree, to catch the rain and convey it to the roots, or to receive the watering which it will be necessary to give it, should the season prove dry.

To cause the Trees to thrive.

The ground where they are planted must be kept cultivated—young trees will not thrive if the grass is permitted to form a sod around them; and if it should be necessary to plant them in grass ground, care must be taken to keep the earth mellow and free from grass for three or four feet distant around them, and, every autumn, some well rotted manure should be dug in around each tree, and every spring the bodies of the Apple, Pear, Plum, and Cherry Trees, and others that it is particularly desirable to promote the growth of, should be brushed over with common soft soap, undiluted with water—this treatment will give a thriftiness to the trees surpassing the expectation of any one who has not witnessed its effect. Should the first season after transplanting prove dry, regular waterings will be necessary; and from a neglect of proper attention in this respect, many lose a large portion of their trees during a drought.

Soil, Culture, &c.

APPLES.

Rich strong loams are the soils most conducive to the growth of the Apple—the roots of Apple Trees being more horizontal than perpendicular, they require a soil less deep than the Pear, and it is on this account that moist soils are more requisite for the Apple, as the roots, extending themselves near the surface, are not benefited by the moisture which is found at a greater distance from the surface of the earth. Apple orchards will, however, succeed on any soil, except a quicksand or a cold clay, if proper attention is paid to keeping the ground in constant cultivation, and manure is regularly dug or ploughed in around the trees. Old well rotted stable manure, decomposed vegetable mould from swamps or woods, and river mud, have been found most suitable for this purpose.

PEARS.

These require a deep light soil, in which their perpendicular roots can easily penetrate—clay, compact, cold, and wet soils, do not suit their growth. When the roots of the Pear penetrate so as to reach the water, the branches become long and slender, and the leaves narrow, changing speedily to a yellowish appearance, and the ends of the branches often perish as if burned. With regard to manuring and keeping the ground cultivated, the Pear requires the same attention as that prescribed for the Apple. This tree is, however, subject to one malady peculiar to itself, commonly called the *Fire Blight*, or *Brulere*, which attacks trees in the most flourishing state, generally commencing at the top or extremity of the branches, and extending downwards. This is caused by a stroke of the sun, which extracts the sap from the uppermost branches of the tree, or from such as are most exposed to its influence, with more rapidity than it can be replaced; or from powerful rays of the sun heating the bark to such a degree as to arrest or nullify the progress of the sap. It is therefore recommended to plant trees in Pear orchards much closer than in those of the Apple. The only remedy against these attacks is to immediately saw off the branches one or two feet below where the blight extends, in which case they generally revive.

PEACHES.

The preferable soil for a Peach orchard is a rich sandy loam, but this fruit will succeed in any soil with proper attention to cultivation and manuring; particular care, however, should be taken not to plant a new orchard on the site of an old one. It may be necessary also to remark, that the ground where they are planted should be kept in a constant state of cultivation, as they become bark-bound and unthrifty the second year after the grass has formed a sod around them. There are two causes which have operated against the success of this tree, and which seem peculiar to it—the one is a *worm* which attacks the tree at the root, near the surface of the ground, and often totally encircles it; the other is a disease usually denominated the *Yellows*.

The Worm.—The most proper course to obviate the depredations of the worm, is to examine the trees every spring and autumn, and to make an application of a mixture of fresh cow dung and clay to the wounds which have been made by them. Lime or ashes thrown around the roots of Peach Trees are found to prevent, in a great measure, the depredations of the worm.

Yellows.—This disease, which commenced its ravages in New-Jersey and Pennsylvania about the year 1797, and in New-York in 1801, and has spread through several of the states, is by far more destructive to Peach Trees than the worm, and is evidently contagious. This disease is spread at the time when the trees are in bloom, and is disseminated by the pollen or farina blowing from the flowers of diseased trees, and impregnating the flowers of those which are healthy, and which is quickly circulated by the sap through the branches, foliage, and fruit, causing the fruit, wherever the infection extends, to ripen prematurely. That this disease is entirely distinct from the *worm*, is sufficiently proved by the circumstance, that Peach Trees which have been inoculated on Plum or Almond stocks, though seldom affected by the *worm*, are equally subject to the *yellows*—and a decisive proof of its being contagious is, that a healthy tree, inoculated from a branch of a diseased one, instead of being restored to vigour and health, immediately becomes itself infected with the disease. As all efforts totally to subdue it must require a long course of time, the best method to pursue towards its eventual eradication, is to stop its progress, and prevent its farther extension—to accomplish which, the fol-

lowing means are recommended, which have been found particularly successful in the orchards of the proprietor, as well as in those of others in his neighbourhood, which continue to produce fruit of the finest quality and in the greatest abundance.

As soon as a tree is discovered to possess the characteristics of the disease, which is generally known by the leaves putting on a sickly yellow appearance—but of which the premature ripening of the fruit is a decisive proof—it should be marked, so as to be removed the ensuing autumn, which must be done without fail, for if left again to bloom, it would impart the disease to many others in its vicinity; care is also necessary, in its removal, to take out all the roots of the diseased tree, especially if another is to be planted in the same place, so that the roots of the tree to be planted may not come in contact with any of those of the one which was diseased.

If your neighbour has trees infected with the yellows in a quarter contiguous to yours, it will be necessary to prevail on him to remove them, that yours may not be injured by them. By being thus particular in speedily removing such trees as may be infected, the disease is prevented from extending itself to the rest of the orchard, and the residue will consequently be preserved in perfect health at the trifling loss of a few trees annually from a large orchard. And here it may be well to remark, that the propagation of the Peach on Plum stocks will only answer where the trees are to be trained as Dwarfs, as it is found that in standard Peaches on Plum stocks, the Peach is apt to overgrow the Plum, and the latter being unable to furnish a sufficient portion of sap to promote the growth of the former, the Peach becomes stinted and short lived; and Duhammel, the most able French writer on the culture of fruits, pronounces the Plum stock never to be eligible for Peach Trees which are intended as standards.

CHERRIES.

Cherry Trees will not succeed in a low wet situation; they thrive best in a rich sandy loam, and the soil around them must be kept cultivated until they have attained a considerable size. If the bodies of the trees become bark-bound, some rotten manure must be dug in around them, and the bodies and largest branches be brushed over with soft soap. The Morello Cherry having become almost extinct in some

parts of the United States, in consequence of an insect which perforates the branches, and produces large excrescences, which, unless lopped off as soon as they appear, soon destroy the tree altogether—it may be satisfactory to state that the English Morello, and the Plumstone Morello, are not subject to this disease—and that the fruit of both of these kinds is far superior in size and flavour to the common Morello, and ripens equally late in the season.

PLUMS, APRICOTS, AND NECTARINES.

For these a light rich soil is preferable, and the same care is necessary as has been recommended for fruit trees generally, in keeping the ground cultivated around them when young; for although it is a common observation, that Plum Trees succeed best in a hard trodden soil, and though such a situation may cause the trees to retain their fruit, still it must be decidedly unfavourable to their growth. Plums, Apricots, and Nectarines, are smooth skinned fruit, and are in some parts of the United States subject to be injured by a small bug called the *Curculio*, which stings the fruit, and causes it to drop before it has attained its proper size. Their depredatians may be effectually prevented by paving round the trees *as far as the branches extend*, as it has been incontestibly proved by frequent experiments made by the proprietor of this garden, and others, that the *Curcilio* will not infest those trees where they cannot find means of immediately concealing themselves in the ground on dropping from the branches. Plum Trees are also subject to injury from another insect, which stings the branches, and causes large protuberances to form on them, which, if not cut off, produce a canker that in time destroys the tree. There are some kinds, however, which are not subject to the attacks of this insect, viz. the Chicasaw, Early Coral, Golden Drop, and other native Plums, the Cherry Plum, Bolmer's Washington, Flushing Gage, Yellow Egg Plum, &c. &c.—And here I will remark, that Duhammel, the highest authority on the cultivation of fruits, recommends Peach stocks as preferable to all others for the free growing kinds of Plums—such as the Green Gage, &c. &c.—as the additional quantity of sap furnished by the Peach stock very much accelerates the growth of the Plum. Still it is necessary, in order to guard against the worm, that they should be grafted beneath the surface of the ground, which, however, is the practice usually pursued.

FIGS.

In the middle and northern states, where the Fig Trees are killed nearly to the ground by the severity of the winters, two crops of fruit may be obtained each season, by planting the early kinds in a warm or sheltered situation, if pains are taken in autumn to bend the trees down, and cover them with earth, sloping the embankment so as to cast off the rain; but, early in April, they should be uncovered and set upright. By this treatment they will produce one crop of fruit early in the summer, and another in September or October.

GRAPES.

Of all the fruits cultivated in the United States, there is none more generally esteemed than the Grape; yet, in the middle and northern states, this fruit is seldom met with in perfection but in cities. The proprietor having attended particularly to the cultivation of the Grape for nearly twenty years past, can confidently assure those who wish to have this fruit in perfection, that they may depend on their vines producing well if they will attend to the following directions; for although a season may sometimes occur when the cold and wet will retard the ripening of the fruit, yet even in the worst seasons a tolerable crop may be calculated on.

There are two causes why the cultivation of the vine has not been successful in the *country*, attention to which is indispensably necessary; *the first* is the proper selection of those kinds which are suitable to the climate, and which come to perfection by the middle or end of September; *the second* is the want of attention to the culture requisite for ripening the wood, which in cities is effected by the dry warm air with little or no care, but in the country, art and attention are required to produce the desired effect. I have, therefore, given the following list of Grapes, with brief descriptions of their qualities, &c. and by reference to page 31, it will be found which are suitable for the *country*, and which will only succeed in the *city*, or in Grape-houses roofed with glass.

1. *Raisin prêcoce de la Madeleine.*—This Grape has small bunches, the berries are also small, and of a dark violet colour, of inferior flavour, and principally desirable for their early maturity; ripens in August.

2. *Early White Muscadine, or Summer Sweet Water.*—This is a round Grape, with a thin skin, and of a delicate flavour. It is a great bearer, and resembles the White Sweet Water in almost every respect, except that it ripens much earlier, being usually in perfection from the 20th to the end of August.

3. *July Grape, Early Black Cluster, or Morillon noir hatif.*—This is a small round fruit, of pleasant flavour, and grows in very compact bunches; it is a good bearer, and ripens in August.

4. *Large Black Cluster.*—This is larger than the above; its juice, however, is rather harsh, and less agreeable to the taste than the preceding one; it is said that this is the Grape from which Port Wine is made; it ripens early in September.

5. *Small Black Cluster, or Burgundy.*—This has oval berries, and is a very pleasant fruit; ripens in September.

6. *Miller's Burgundy, Black Cluster, or Meunier.*—This is a small black Grape, rather of an oval form, and grows in short compact bunches; the juice is sweet and pleasant; it is a great bearer, and a good Grape for Wine; ripens in September.

7. *Auvergne, Pineau, or True Burgundy, sometimes called Bourguignon.*—This is rather an indifferent fruit for the table, but in Europe considered one of the best for making Wine; it is of a middle size, and somewhat oval; ripens in September.

8. *White Sweet Water.*—This has very large round white berries close on the bunch, which is of a good size, the skin and flesh are very delicate, and replete with very agreeable juice; the berries on the sides of the branches next the sun are often clouded with spots of a russet colour. This Grape flourishes admirably in our cities, where large quantities are annually sold in the shops; some bunches which grew in the garden of Edward Probyn, Esq. during the summer of 1821, were of uncommon size, one of which weighed 1 *lb.* 10 *oz.* and was 17 inches in girth; in fine seasons it succeeds in the country also.

9. *Black Sweet Water.*—This is a roundish fruit, growing in small compact bunches, is very sweet, and ripens in September.

10. *Black Madeira.*—This Grape I received direct from Madeira; it produces abundantly, and is one of those that agree best with our climate; the fruit is very juicy and of a

pleasant flavour, and seems well calculated both for Wine and the table; it ripens in August.

11. *Purple Madeira.*—This is a small pale purple Grape, loosely set on long bunches; they have a vinous perfume and flavour when ripe, but are not suitable for the table.

12. *Bordeaux Purple.*—This Grape I received direct from Bordeaux a few years since; it produces very abundantly, and the fruit, which is round, is of a pleasant flavour and very juicy, though but of a middle size; it ripens early in September.

13. *White Frontignac, or Muscat blanc de Frontignan.*—This has large long bunches of a conical form; berries round and very close; colour white, skin thick, juice luscious and musky, and of exquisite flavour; perhaps no Grape is superior to this as a table fruit; ripens in September.

14. *Grizzly Frontignac.*—The berries are round, tolerably large, colour brown, red, and yellow intermixed, and they have a high musky perfumed flavour; ripens in September.

15. *Black Frontignac, or Muscat noir.*—This has very large round fruit, covered with a meally bloom, and of a very fine flavour. It is called, at the Cape of Good Hope, *the Black Constantia;* ripens in September.

16. *Red Frontignac, or Muscat rouge.*—Berries less close than No. 13, and of a less size, colour lively red, skin thin, and of a musky flavour; ripens better than the white, but is not equal to it; ripe in September.

17. *Blue, or Violet Frontignac, or Muscat violet.*—The branches of this Grape are small, the berries are also small and loosely set, and of a black colour, powdered with a fine violet bloom, and possess a most delicious flavour; ripens in September.

18. *White Muscat of Alexandria, or Alexandrian Frontignac.*—The bunches are long, the berries not closely set, but large, oval, and yellow, and of a very fine musky flavour.

26. *White Chasselas, Royal Muscadine, D'Arboyce, or Chasselas blanc.*—This has round amber-coloured berries, of moderate size, thin skin, and soft juicy flesh; the bunches are very large, and frequently weigh from 6 to 7 pounds.

27. *Red Chasselas, or Chasselas rouge.*—This is very like the above in size and shape, but of a dark red colour; it is a good Grape, but ripens later than the white.

29. *Musk Chasselas, Chasselas musqué, or Frankindale.*—This has a large round green berry, sweet, and of a musky flavour.

38. *Black Hamburg.*—The berries are large, black, and inclining to an oval; they hang loosely on the bunches, which are well formed; the skin is thick, but the flavour good, and it is a great bearer, on which account it is much esteemed; ripens in September

39. *Red Hamburg, or Gibraltar.*—The berries are dark red, skin thick, flesh juicy and delicate; the shape of the berry and form of the bunch both resemble the foregoing.

40. *Parsley leaved, Cioutat, or Raisin d'Autriche.*—This is a variety of the Chasselas, with leaves finely divided, but of which the bunches and fruit are rather smaller; the flavour is fine, the skin thin, and the flesh delicate and juicy.

41. *French Chocolate coloured.*—This was received from France about thirty years since; the vine is of very vigorous growth, and a great bearer, and seems to suit our climate well, and to be as hardy as our native wild Grapes; the fruit is oval, of a sprightly flavour, and the bunches large; it is an excellent Wine Grape, as well as an agreeable one for the table; it ripens from the middle to the end of September.

42. *Red Muscadel.*—The berries are very large, oval, of an equal size throughout the bunch, and of a beautiful red colour; the skin is thick, and the flesh hard; the bunches frequently weigh from five to six pounds.

46. *White, or true Tokay.*—The berries are somewhat oval, and closely set on the bunch, which is of moderate size; the skin is thin, and the flesh delicate, abounding with very agreeable juice.

47. *Lombardy, flame coloured Tokay, or Rhenish.*—The berries are large, oval, and of a fine flame colour; the bunches regularly formed with shoulders, and frequently arrive to the weight of 6 or 7 pounds.

48. *Malvoisie, Malmsey, or Blue Tokay.*—This has small berries, rather oval, and of a brown colour, powdered with a blue bloom; the skin is thin, the flesh delicate, and replete with vinous juice.

54. *St. Peter's, or Sainte Pierre.*—A large and very fine black fruit, of a somewhat oval form; the skin is thin, the flesh very delicate and juicy, and the bunches large.

55. *Bland's Grape.*—This is a round fruit, of a pale red colour, middle size, and very pleasant flavour; it is an agreeable table fruit, and is also said to make excellent Wine. It has been supposed for many years to be a native of Virginia, but I have recently received information which cannot be doubted, through Dr. Norton, of Richmond, that this Grape

was introduced many years since into Virginia from Italy, by a Mr. Mazzei, and carried thence to Philadelphia by Mr. Bland, and indeed the general aspect of the plant proves it to be an exotic Grape; it ripens in the beginning of October.

56. *White Cornishon, or Cornishon blanc.*—The berries are very long, and swelled in the middle, not closely set on the bunches, but white, sweet, and excellent.

57. *Syrian.*—The berries are large, white, and oval; skin thick, flesh firm, and the bunches well formed and enormously large, sometimes weighing above 12 pounds, and making a most beautiful appearance. Although this Grape is inferior to some others, still, as it is very prolific, it merits a place in every collection.

105. *Isabella Grape.*—This is an American Grape, a native of Dorchester, South-Carolina, and was introduced to this state by Mrs. Isabella Gibbs, the lady of George Gibbs, Esq. of St. Augustine, who then resided at Brooklyn, Long-Island, and in honour of that lady has been called *Isabella Grape.* It is a dark purple fruit, of a good size, oval form, and juicy, and nearly equals some of the European kinds; and, for vigour of growth and an abundant yield, exceeds any other yet cultivated in this country, and requires no protection during the winter season. General Joseph Swift, of New-York, informed me that a single vine in his garden produced above eight bushels during each of the seasons of 1820 and 1821. This Grape promises to rival all others in cultivation in this country for the purpose of making Wine, as it possesses all the requisites to ensure success in making Wine of a fair quality, or for making Brandy equal to that of France; it ripens in September.

106. *Scuppernon.*—This Grape has been cultivated with great success in North-Carolina, of which state it is a native, and where many hogsheads of Wine are annually made from it. The Wine is of a very agreeable and peculiar flavour. It will no doubt be ere long cultivated extensively throughout the United States for the purpose of making Wine, as the experiments in North-Carolina, which, in some cases, have been on quite an extensive scale, have realized the most sanguine wishes of those who commenced the undertaking.

107. *Alexander's, or Schuylkill Muscadel.*—This Grape, which has been erroneously called at the Spring Mill Vineyard, and at Philadelphia, the *Constantia*, or *Cape of Good Hope* Grape, is unquestionably a native of our own country, and originated in the vicinity of Philadelphia. The berries

are black, very sweet, and of a slight musky flavour, but contain a pulp. Wine of a fair quality has been made from this Grape in different sections of the Union; and Mr. Adlum, of the District of Columbia, has succeeded in making a Wine from it very similar to Burgundy.

108. *Orwigsburg.*—This is a native white Grape, sweet, with a thin skin, and larger than the *Meunier;* it is very hardy, yields abundantly, and is highly esteemed even by connoisseurs. I am informed by Dr. William E. Hulings, of Philadelphia, (a gentleman distinguished for his philanthropy and for his zeal in introducing to notice such fruits as promise permanent advantage to our country,) that this Grape was discovered about three miles from the town of Orwigsburg in Pennsylvania, and by him named after the place of its origin; ripens early in September.

109. *Elsingburg.*—For the dissemination of this Grape we are also indebted to Dr. Hulings, of Philadelphia, who brought it about seven years since from Salem county, New-Jersey. The berries are blue, large, and juicy, and it promises to be an excellent Wine Grape; the vine is also extremely hardy; ripens early in September.

114 and 115.—These two varieties of the Grape, (*see page* 34,) which are said to be very fine, and to succeed admirably, I received from my valued correspondent, Dr. Norton, of Richmond, whose acute observation and zeal in bringing meritorious fruits into notice, promises much benefit to our country—to one, which was discovered in Prince Edward county, Virginia, he has given the name of *Prince Edward Grape*—to the other, which is a seedling from Bland's Grape, and for bringing which into notice our country is particularly indebted to Dr. Norton, I have given the name of *Norton's Virginia Seedling.* Both kinds are now under successful cultivation.

The great object being to introduce into cultivation, in the middle states, those Grapes whose character particularly assimilates to the climate, and such as come to maturity not later than the month of September, I have made it a point to import from Germany all the finer varieties of Table and Wine Grapes which support the winters of that country without protection, and have received, besides those named in the Catalogue, a number of others, the names of which will be published in the next edition.

Of Grapes suitable for states south of the Potomac, the collection is complete; and all the Grapes celebrated for

Wine or for the table, in the vicinities of Marseilles and Malaga, will be found in the Catalogue.

CULTIVATION OF GRAPES.

Soil and Situation.

The Grape delights in a deep light soil, where the roots can penetrate to a great depth with perfect facility. It flourishes in gravelly soils, where the land is rich and not heavy, and will even scarcely fail to grow vigorously in any land except a hard clay. The ground should, however, be made perfectly mellow to the depth of two feet, and if not naturally rich, should be made so with old well rotted stable or cow-yard manure, the latter always preferable. The situation should have a southern aspect; an eastern aspect is found to render the fruit and foliage most liable to mildew, and a south-west exposure is found to be preferable to all others.

Transplanting.

Either the spring or autumn answer for transplanting vines, but the latter is the preferable season. In removing the vines it is necessary to keep the roots moist from the time they are taken up until replanted. Let the holes be dug eighteen inches deep, and some well rotted cow-yard or stable manure be incorporated with the earth that is filled in around them, and let them be watered as soon as they are planted.

Pruning.

About the first week in November it will be necessary to prune the vines; if they are quite young, the branches of the same season's growth should be trimmed down to about four buds, but, as the vines advance in age and size, the number of buds to be left may be increased, and when the vines are quite strong, some of the most vigorous shoots may be left from four to six feet in length; observing always in pruning to proportion the number of buds left to the strength of the shoot. In the spring many unnecessary shoots will be produced, which must be rubbed off, as they would exhaust the vine, and lessen the quantity and quality of the fruit; indeed, care should be taken to rub off all such buds as are unnecessary to furnish bearing shoots for the ensuing year, and to lop off such lateral branches as would tend to draw the sustenance from the main shoots.

Training.

Lattice fences, five feet high, and at a distance of six feet from each other, answer extremely well for vines, which should be planted along them at the distance of six feet asunder. On these

fences the shoots should be trained in a horizontal or oblique direction, and each branch singly, so as to allow the air to pass freely through, and cause the wood to ripen well, on which invariably depends the success of the ensuing crop. At Thomery, a town near Paris, celebrated for its fine Grapes, the vines are trained on trellices eight feet high. These lattices possess this advantage, that the sun can shine on both sides of the vines in the course of the day, and that they allow a free passage to the air, which is of great benefit as well in maturing the fruit, as in ripening the wood. In some parts of France, however, where the culture of the vine is carried to so great an extent, a very simple mode is pursued, which is to place two poles to each vine, and to train up two shoots to each of the poles. This method might probably be found advantageous in this country on the principle of economy, when it is contemplated to establish extensive vineyards.

Culture, &c.

It is preferable in winter to protect most kinds of foreign Grapes in the following manner, though there are many which do not require it:—In the course of the month of November, after they have been trimmed according to the above directions, bend each vine gently down, then stake it to keep it in its place; after this, proceed to cover it with earth or litter, hilling the earth up well around, and sloping it to cast off the rain. In the beginning of April, they must be carefully uncovered, and trained along the lattices designed for them, or tied up to the poles in such a way that the branches are kept separate from each other, and, if it is the first season after transplanting, allow but three or four of the most vigorous buds to grow, and rub off the others. It has been urged by some, that the necessity for covering most kinds of foreign vines precluded their culture for the purpose of making Wine; but it must have been unknown to them, that the vineyards on the Rhine, where large quantities of Wine are made, are treated in this manner. However, even this objection may be remedied by planting only those vines which are cultivated in the north of France, and which there withstand, without protection, a degree of cold full as great as that of the middle states; the new varieties which have originated in our own country bid fair also to do away every difficulty on this point. The ground around the vines must be kept mellow, and free from grass and weeds; and, every autumn, immediately after pruning them, it will be necessary to have from two to four shovels full of old well rotted manure dug in around each vine. It is to be understood that the directions for covering the vines during the winter, and the selections of early fruit, &c. are only necessary for the climate north of the Potowmac; for in the more southern states, no protection of course is necessary, and all the later kinds of Grapes may may be cultivated with every reasonable prospect of success; but all the other directions relative to pruning, training, manuring, &c. will be found necessary as well in a southern as in a northern clime.

GOOSEBERRIES.

This is a fruit generally planted, but from the necessary culture not being understood, few succeed in having them produce plentifully, and the fruit fair and of good size. To effect which, one third of the old wood must be regularly trimmed out every autumn, by which means a succession of thrifty bearing wood will be kept up, as the fruit is produced on the young shoots of the previous year's growth, and it is also necessary every autumn to dig in a plenty of old well rotted manure around them This treatment will cause them to grow strong, and the fruit to be large and fair. In point of situation a northern aspect is preferable, and the fruit will be twice the size, if they are planted against a north fence or in any other situation where they are sheltered from the intense heat of noonday, which when differently situated often scorches the fruit to such a degree, as to entirely stop its growth.

ORNAMENTAL FOREST TREES AND SHRUBS.

For all hardy Forest trees, except Evergreens, autumn is the preferable season for transplanting; if taken from a nursery, they are naturalized to an upland soil, but if taken from the woods or swamps, they should be planted in soil similar to that from which they are removed. Forest, as well as Fruit trees, to cause them to grow thrifty, require the ground to be kept cultivated around them; and when the bodies become bark-bound or mossy, they should be brushed over with soft soap, as directed for Fruit trees, especially the Mountain Ash, which sometimes becomes covered with white insects and their eggs; these should be scoured off first, before the soap is applied, or at the time of applying it.

WHITE CHINESE, *or Italian Mulberry.*

This is the species which has always been cultivated for rearing silk worms. It is originally from China, but, from being so extensively cultivated in Italy, it is more generally called the Italian Mulberry. This tree is very easy of cultivation, and of very rapid growth, and may be reared to any extent without difficulty, as it agrees so well with our climate, that they are found growing spontaneously in the hedges on Long-Island, from seeds which have been scattered by the winds or birds.

ENGLISH AND SPANISH FILBERTS.

These nuts, which are vended in large quantities in our markets, grow as well in our climate as the common hazelnut, and produce very abundantly. Such being the case, it is hoped, ere long, sufficient will be produced from our own soil to supersede the necessity of importation, as plantations of this tree would amply remunerate the possessor, or, if planted as a hedge, would be found to be very productive. A single bush of the Spanish filbert in my garden produces a half bushel annually.

COMMON LOCUST.

Within a few years, many of our enterprizing landholders have been devoting their attention to planting extensive tracts with this tree, the wood of which is in so much request in ship building. An acre of these trees planted at two feet distant each way, will contain 10,890—at three feet distant, 4,840—and, at four feet distant, 2,722—and it is said no appropriation of land is more lucrative than that devoted to this purpose.

LIQUORICE.

The *Glycyrrhiza glabra*, or Liquorice, may be cultivated to equal perfection in the United States, as in any other country. It delights in a light rich sandy soil, and the product is so great, that it would yield an immense profit to the cultivator. Such being the case, it is to be hoped that the time is not far distant when we shall not have to depend on England and Spain for our supply.

DYER'S MADDER.

This plant, of so much importance in manufactures, and of which we have annually to import large quantities from Holland, will succeed in this country as well as in any part of Europe. It will thrive in any soil except a sand, and would amply remunerate those who would undertake its cultivation on a large scale, as the daily increase of our manufactories will cause an enlarged demand for this indispensable article.

ROSES.

No class of plants, so easy of culture as this, yields more intrinsic delights to the amateur; the diversity of size, colour, fragrance, and form, have been varied by art to an almost infinite degree, and in one collection alone in Europe, above 1200 varieties are enumerated. Since the previous part of this Catalogue was put to press, near 300 new varieties have been received, and the collection at this establishment now exceeds 500 varieties, including above 50 kinds of China Roses and nine varieties of the Moss Rose, among which are the Striped Moss, Scarlet Moss, Mossy Rose de Meaux, &c. Enduring the rigour of the severest winters unmjured, and yielding with so little attention such a rich accumulation of beauty and fragrance, every garden should possess at least all the more conspicuous varieties of this unrivalled flower; and it is hoped, ere long, we shall see the fashion followed in this country, which has for years prevailed in England, of training the hardy varieties of the Chinese Everblooming Rose against the sides of our country houses and cottages, as the profusion of flowers which they daily afford from spring to autumn, gives to the retirement of these rural scenes a degree of Floral enchantment, and throws an air of magic round the spot.

YELLOW ROSES.

Some complain that the double yellow Roses do not flower well; it is therefore proper to remark, that they require an airy situation, and a gravelly soil, and that every autumn, one half of the old wood should be cut down within four inches of the ground; by this means a succession of thrifty blooming shoots will be kept up. The single yellow, and the red and yellow Austrian, it is well to treat in the same manner, though they bloom freely in almost any soil, and with little or no care.

EVERGREEN TREES AND SHRUBS.

These, if taken from the woods, should be planted in winter with balls of frozen earth; but, if taken from a nursery, where they have been naturalized to an upland soil, the preferable season for many kinds is the spring, as some Evergreens fail when transplanted in autumn, especially if the earth falls entirely from the roots, and the frost penetrates to the earth below them when planted, which it seldom fails to do in the northern and middle states; this, however, may be remedied by strewing litter around them, to prevent the frost penetating to the roots.

ASPARAGUS.

This plant, which is cultivated very extensively for the markets, requires that the soil be made very rich and light, and that it be made mellow to the depth of eighteen or twenty inches. The preferable mode of planting is in long narrow beds of about five feet wide, and the plants should be placed one foot apart each way in the beds.

STRAWBERRIES.

Since the publication of the list of Strawberry plants at page 30, I have succeeded in importing alive at the sixth effort, the following new varieties, several of which, from their great size, productiveness, or flavour, have been figured and described in the transactions of the London Horticultural Society, as worthy of particular notice:—

Kean's large	Bath scarlet
Kean's Imperial	New hautbois
Roseberry, *very productive*	Knights No. 14
Large Downton	Knights No. 6, *largest*
Black	

As beds of Strawberries generally want renewing every two or three years, it will be necessary in forming the new beds to select the plants in the proportion of nine bearing plants to one barren; and, in order to do this with certainty, it will be well to transplant them immediately after the fruit has matured. If, however, your beds are not encumbered with a superfluous number of barren plants, this precaution will not be indispensably necessary; though

it is generally requisite with the English Hautboy, which is apt to produce a great proportion of barren plants, and even without proper attention, beds of this and of some other kinds will become almost totally unproductive.

CARNATION PINKS.

The collection of these has been greatly extended, and now comprises above one hundred splendid varieties, of which by far the larger proportion are of that description called *whole flowers*, to distinguish them from the *bursters*, and of the class denominated *rose leaved*, on account of the border of the petals being smooth, the latter have for the most part been received from the Royal Garden at Paris, through the polite attention of the enlightened administrator of that splendid establishment. They should be covered in severe winters with a box or frame, or taken up with balls of earth, and planted during the winter under a common hot-bed, with or without glass, as they bear cold, but not cold and moisture at the same time.

GREEN-HOUSE PLANTS.

Among the plants which have hitherto been introduced to this country, none exceed those which have been received from China and Japan; in the former of which countries they are said to excel all other nations in the cultivation of flowers. It is also a happy circumstance, that nearly all the plants which have yet been received from either of those countries, are among the hardier kinds of Green-house plants, and succeed with very little attention; and, indeed, a number of them are found to withstand the winters of the middle states. It being, therefore, so desirable an object to obtain all the valuable plants of those countries, arrangements have been made to procure such as have already found their way to Europe, as well as to add annually to the collection by importations direct from China.

ORANGE AND LEMON TREES, &c.

The Orange, Lemon, Citron, Shaddock, and Lime, are easily cultivated, and no trees will bear hardier usage, if they are only secured from cold and frost. They may be removed every month in the year, and yet grow well with the aid of shade and moisture. Early in October they should be taken out of the boxes or pots in which they are growing, with the balls of earth entire, and have the sides and bottom shaved off about an inch deep with a sharp knife, to make room for fresh earth, and then replace them in the pots or boxes, first covering the holes at the bottom with shells or broken earthern, and some fresh compost; then fill in around the

tree with the compost prepared as hereafter directed. If, in the course of replanting, the earth should have been much separated from the roots, the tree should be placed in a shady situation for a few days. If it is desirable to promote the growth, and to form large trees, then let boxes be made a size larger at every annual transplanting; but, if the boxes should be too large in proportion to the tree, fruit will not be produced so soon, nor in as great a quantity.

Compost for Orange Trees, and most other Green-House Plants.

Take one third good rich earth, one third well rotted stable manure, and one third swamp, or wood mould; but, where swamp mould cannot be procured, let two thirds be good rich earth; these must be well incorporated together, and if mixed a few weeks previous to the time of using, it will be the better for it. This soil will suit all except Succulent Plants, such as the different species of Aloe, Cactus, Yucca, Stapelia, &c. which require a composition of half coarse gravel or lime rubbish, one fourth swamp mould, and one fourth common garden mould.

CAMELLIA JAPONICA, *or Japan Rose.*

Much as we are indebted to Japan and China for elegant plants, still we are more peculiarly so for the different species and varieties of the Camellia, which, for the many beauties it concentrates, may emphatically be styled "the Queen of Flowers." The different varieties of this plant form the most brilliant display of the Green-house from December to May, and the splendour of their flowers, and richness of their foliage, are surpassed by no others. The flowers of many of them equal in size the largest garden Rose, and combine a regularity of form, and richness of colouring, which present an admirable contrast with their dark shining green leaves, and render them the greatest ornaments of a room or the Green-house. They need less protection than almost any other Green-house plants, and four of them, which were left in the open ground during the winter of 1821, and which were protected merely by a common frame, received no injury, although the ground in the frame was frozen to the depth of five inches.

PÆONIA MOUTAN, *or Tree Pæony.*

In the gardens of China, they cultivate 240 varieties of this splendid plant, some of which are sold as high as a hundred ounces of gold; and in so much esteem is it held by them, that it is there called "the King of Flowers." During the months of March and April, this plant appears in its most magnificent garb, and its flowers, which are from eighteen inches to two feet in circumference, form, what is so rarely met with, a combination of splendour, delicacy, and fragrance. It is one of the hardiest Green-house plants, and will live if protected only by a common frame, and will probably be found to stand our winters in the open air.

Besides the above, we are indebted to China for three splendid Herbaceous Pæonies, which are perfectly hardy, viz.—

Pæonia sinensis Whitleii, with very splendid double white, or sulphureous yellow flowers, afterwards changing to white, and whose external petals are generally tinged with red; the flowers are of a very large size, the stems are usually three feet high, with from two to three flowers on each.

Pæonia Humei, with very large double crimson flowers, of brilliant appearance, and a pleasant odour; flower-stems also grow to the height of three feet.

Pæonia fragrans, with rose coloured sweet scented flowers. This blooms the latest of all, and the flowers are generally in cymes of two or three on a stem.

GREEN AND BOHEA TEA.

These are very hardy Green-house plants, and would no doubt withstand the winters of any part of the Union south of Wilmington, N. C. The leaves of the Green tea are more than double the size of the Bohea, and both produce fine flowers in abundance, and are cultivated with as much ease as any of our commonest trees. It is said that all the finer teas are perfumed by the Chinese with the delightful flowers of the Olea fragrans, or Fragrant Chinese Olive.

EUROPEAN OLIVE.

The cultivation of this tree, which has always been considered as a source of incalculable wealth to those countries where it has flourished, has latterly attracted the attention of many persons in Florida and other southern sections of the Union, where there can be no doubt it will succeed as well as in southern France or Italy. It is a beautiful evergreen, and flourishes with very little attention.

PYRUS JAPONICA, *or Scarlet Flowering Japan Apple.*

This is also a very desirable plant; its flowers, which are produced in clusters during most of the winter season, are of the most brilliant scarlet, and are succeeded by small fruit; it is found to be perfectly hardy, and to bear exposure during the severest winters; there is also a beautiful white flowering variety.

CHINESE MAGNOLIAS.

Magnolia obovata, is esteemed for the uncommon richness and beauty of its flowers, which are produced in March, and are of a delicate purple outside and white within, and it will also stand the winter in the open air.

Magnolia conspicua, with large white flowers, which are very splendid and shaped like a chandelier, flowers in March.

Magnolia fuscata, with olive coloured flowers, quite small, but of a most delightful fragrance.

Magnolia annonæfolia, with longer leaves than the above, and flowers somewhat similar, and equally sweet.

Magnolia pumila, a pretty dwarf species, with fine foliage, and very fragrant white flowers.

GARDENIA FLORIDA, *or Cape Jasmine.*

This is also a justly admired plant; the bright shining green of its foliage, and the delightful odour of its large snow white flowers, which are produced from June to December, must ever render it one of the most esteemed exotics. There are three varieties, the single flowering, the double small leaved, and the double broad leaved; the latter is by far the most common; also the dwarf or radicans, with double flowers; they are all equally beautiful and fragrant.

CHINA ROSES.

It will be seen by the Catalogue, that the collection of these equals, if not surpasses any other in the world; and no variety is known to exist which is not already in this garden; among them, however, none merits more particular attention than the *Rosa odorata* or *Tea scented rose*, which yields a great abundance of flowers of the most exquisite fragrance There are several other varieties which are fragrant in a less degree; the *Dwarf or Pompone* is admired for its very small delicate flowers and foliage; the *Lawrencia* for being the most diminutive rose known; the *Resplendent rose* has very fine dark full double flowers of small size; the *Speciosa* has very large full double flowers, which often have buds in the centre; the *Subalba* is a fine double rose, nearly white; and the *Macartney rose* is pure white with yellow stamens; the *Blush changeable*, is so called on account of the flowers varying in colour after expansion; the *Sanguinea* produces abundance of fine dark crimson flowers; among the others each has its particular claims to our admiration; and the *Multiflora* of different kinds, the *Roxburghii*, *Grevillii*, *Banksiæ*, *Champneys*, *Nosette*, *Herbemont*, *Tranguillana*, *Macartney's*, *and Lævigata*, are suitable for training against the sides of buildings.

CORCHORUS JAPONICUS, *or Double Japan Globe Flower.*

This shrub, although cultivated as a Green-house plant, will, nevertheless, thrive in the open garden. In the windows of a warm room, or in a Green-house, its slender branches are, during the months of February and March, bent down with the weight of its numerous flowers, of a golden yellow, which are produced in wreaths; and there is scarcely a week, from spring to winter, that flowers may not be found on it, especially if it is planted during that season in the open ground, or continued there throughout the year.

CHINESE HIBISCUS.

Hibiscus mutabilis, flowers in November and December, they are the size of a large garden rose, and their peculiarity consists in their

changing from white to blush colour and then to purple, thereby presenting to view flowers of three different colours on the same plant.

Hibiscus rosa sinensis, the different double varieties of this shrub are extremely beautiful, perhaps none more so than the double crimson, which has a richness rarely excelled; the different varieties of this plant are among the most desirable appendages of the Green-house.

DATURA ARBOREA, *or Great Peruvian Datura.*

This plant, which is of vigorous growth, produces very splendid flowers during the months of October and November; they are pure white, of a pentangular form, with angular extensions, possess an agreeable fragrance, and are generally near a foot in length.

DAHLIA.

Of this beautiful plant, more than 150 varieties are now cultivated in Europe, many of which have double flowers. It is a native of Mexico, and the flowers are of every gradation, from the darkest lake colour to the lightest shades, and of every hue but green, and in splendour they are surpassed by those of no other plant.

The roots, which are tuberous, resemble a sweet potato, and can be taken up in the fall, and planted in boxes or pots until spring, when they can either be retained in the pots, or replanted along the borders of the garden; the latter situation is however preferable, as their growth is there so much more vigorous, and the flowers consequently more abundant. The middle or end of April, is the proper season for planting them out, when they will soon shoot up to the height of from five to eight feet, producing a great abundance of flowers, of which from thirty to forty are frequently in bloom on a single plant at the same time. The single flowering ones possess very vivid colours; but the double ones, from being the most rare and splendid, are the most esteemed. The collection now in the possession of the proprietor, is not surpassed by any in the world, and consists of 73 double varieties. See page 102.

CONCLUSIVE REMARKS.

It will be perceived by persons who are connoisseurs of flowers, that very extensive acquisitions have been made to the Green-house collection of the most rare, beautiful, and valuable species, and in doing this, the proprietor has rather consulted the aggrandisement and extension of the establishment, than a particular regard to pecuniary benefit to himself; and very many of the plants have been purchased at an expense of from one to five guineas each.

DIRECTIONS

FOR THE

CULTURE OF BULBOUS AND TUBEROUS FLOWER ROOTS.

Situation.

A southern aspect, dry and airy, and sheltered from the north winds, is preferable for most Bulbs, but Anemones and Ranunculuses will do best in a situation which, combining a southern aspect, is at the same time sheltered from the intense heat of a noonday sun.

Soil.

One third common sand, one third old well rotted cow-yard manure, and one third good garden mould; let the beds thus formed be well pulverized to the depth of 15 or 18 inches, that the three component parts may be completely mixed together; a fourth part of rotten wood, or decomposed vegetable mould from a wood or swamp, if convenient to be had, may be added with advantage to the above, and will at all times be beneficial in giving additional lightness to the soil; and, when thus prepared, the soil need not be removed for five or six years. The beds should be raised four to six inches above the level of the walks, which will give an opportunity for all superfluous moisture to run off; some sand strewed in the trenches, both before and after placing the roots, would be of advantage.

Time of Planting.

For Hyacinths, Tulips, Crown Imperials, Lilies, Poleanthus Narcissus, Common Narcissus, Jonquils, Irises, Crocuses, Colchicums, Star of Bethlehem, Winter Aconites, Snowdrops, Snowflakes, Gladiolus, and most other hardy Bulbs, the preferable season for transplanting is the months of August, September, and October; and it would be well here to observe, that the above mentioned bulbs (Tulips excepted) will thrive best if not taken from the ground oftener than every second or third year.

The Ranunculus and Anemone are not so tender as is generally supposed; they may either be planted in October or November, in a warm situation, and be protected during winter by a covering of three or four inches of leaves or tanner's bark, or they may be kept in dry sand during the winter season, and be planted in March or April. To have a succession of flowers, a proportion may be planted in autumn, and the residue in the spring; and, if treated as above directed, very little care is necessary to have them flower in perfection.

The different species of Ferraria, Antholyza, Ixia, Crinum, and Hæmanthus, the tender kinds of Amaryllis, Pancratium, and Gladiolus, with most other delicate Bulbs, may be planted during the months of November or December, in pots, when intended to be sheltered during winter, or they can be kept in dry sand until the months of March or April, and then be planted in the open ground, when it has become free from frost, and perfectly settled.

Depths and Distances.

Hyacinths, Martagon, and other large Lilies and Pæonies, should be planted at a depth of four inches; Crown Imperials, and Poleanthus Narcissus, six inches; Tulips, Double and Single Narcissus, Jonquils, Colchicums, and Snowflakes, three inches; Bulbous Irises, Crocuses, Arums, small Fritillaries, Pancratium, Gladiolus, and Snowdrops, two inches; Ranunculuses, Anemones, and Dog's Tooth Violets, one inch; always measuring from the top of the Bulb. The rows should be about ten inches apart, and the roots be placed from four to six inches apart in the rows according to their size.

Protection during Winter.

On the approach of winter, it would be beneficial to cover the beds with tanner's bark, withered leaves, or light rotten earth from the woods, such as is formed by the decay of leaves, to the depth of two or three inches, as it prevents any ill effects which a very severe season might have on the roots; but it should be carefully raked off again early in the spring.

Taking up Bulbs after blooming.

The only advantage to be gained by taking up Hyacinths and other Bulbs, (*Tulips excepted*) is either to divide the roots when they have become too numerous, or to renew a worn out soil, neither of which can occur oftener than once in three years; with Tulips, however, it is different, for as the fine and delicate tints they possess, do not originate with the rearing of the plant, but are the result of art practised in their after cultivation, and as variations of colour thus produced, are rather the effect of disease in the plant, than of any other cause, it is necessary to continue the course of annually taking up the roots of all the finer varieties, in order to preserve their beauty in perfection; Tulips may be kept from the ground two weeks or more at the option of the owner; but Hyacinths and other roots, it is preferable to plant as soon as they are separated, and a fresh bed prepared according to directions already given.

About a month after the bloom is passed, the foliage puts on a yellow decayed appearance. This is the proper season for taking them up; on doing which, you must cut off the stem and foliage within an inch of the bulb, leaving the fibrous roots attached to it. After thus preparing them, they must be spread singly in an airy room for two or three weeks to dry; and then each root must be wrapped carefully in paper, or put in dry sand until replanted.

Hyacinths, and other Bulbs, to bloom in pots or glasses.

For this purpose, single Hyacinths, and such as are designated as earliest among the double, are to be preferred.—Double and single Jonquils, Poleanthus Narcissus, and double Narcissus, also make a fine appearance during the winter season.

Bulbs intended for blooming in pots during the winter season, should be planted during the months of October and November, and be left exposed to the open air until it begins to freeze, and then be placed in the Green-house, or a warm room. They will need moderate occasional waterings, and should be exposed as much as possible to the sun and light, to prevent the leaves from growing too long, or becoming yellow.

Those intended for glasses should be placed in them about the middle of November, the glasses being previously filled with pure water, so that the bottom of the Bulb may touch the water, then place them for the first ten days in a dark room, to promote the shooting of the roots, after which expose them to the light and sun as much as possible; the water should be changed as often as it becomes impure, and care be taken not to suffer it to freeze.

REMARKS.

TULIP—*Tulipa gesneriana.*

In no class of plants has nature so varied her delicate tints as in this; it would seem as if each change which nature or art is capable of forming, was included in the varying beauties of the Tulip, above 1,100 varieties of which are cultivated in some of the gardens of Holland. All the finer varieties, however, of this delightful flower, have been obtained, by cultivation and art, during the last two centuries, through the perseverance of the Dutch, French, and Flemish florists; several kinds of which possess a delightful fragrance, although persons who are ignorant of this circumstance, have made the want of it an objection to this splendid flower.—About the middle of the seventeenth century the rage for the Tulip was so great in Holland, that from four to twenty-five thousand florins were given for a single root. The Tulip called *Semper Augustus* was sold for ten thousand florins, ($ 4,000,) and the one called *Viceroi*, for twenty-five thousand florins, ($ 10,000.) This extraordinary traffic was, however, soon checked by the interference of the Legislature, who enacted that no Tulip, or other flower, should be in future sold for a sum exceeding about fifty guineas; and so effectual has been this law, that at present the highest price of any Tulip in that country is only one hundred

and fifty florins, ($ 60,) and the highest priced Lily three hundred florins, ($ 120.) Tulips are divided into early and late blowers; the former begin blooming about the 15th of April, and are followed by the latter kinds in succession until the end of May; the late kinds produce the largest flowers, the stems of which are generally from twenty to thirty inches in height.

HYACINTHS—*Hyacinthus orientalis.*

This favourite flower, which, with its great beauty, combines also the most exquisite fragrance, has been cultivated in Holland to an equal extent with the Tulip, and 1,300 varieties are found in the gardens of that country. The first double Hyacinth known in Holland was raised from seed about the end of the seventeenth century, by Peter Voorhelm, from which all the fine double varieties we now possess may be traced. So great was the value of a fine double Hyacinth formerly in Holland, that from two to ten thousand florins were given for a single root; and Mr. Dutens mentions, that in his travels, in that country, 1771, he saw ten thousand florins ($ 4,000) refused for a single Bulb. So extensive has their cultivation, however, now become, that many acres are occupied by individuals solely for that purpose, and many hundred thousand roots are annually exported to other countries; and the prices have been so reduced, that no Hyacinths are now sold at more than one hundred florins each, and few higher than from two to five guineas, and by far the greater number at much less rates. Single Hyacinths are held in less estimation than double ones; their colours, however, are more vivid, and their bells, though smaller, are more numerous; they are preferable for flowering in winter to most of the double ones, as they bloom two or three weeks earlier.

It has been supposed by many that Hyacinths, Tulips, and other Bulbous Flowers, are difficult of culture, and that our country being unfavourable to their growth, they would dwindle and decline after a few years' cultivation. This is altogether a mistaken impression; and, if it ever occurs, must be owing to improper treatment, as no country in the world possesses a climate more congenial to the culture of Bulbous Flowers than the middle states; for the disadvantages of great fogs and a humid atmosphere, which are so much complained of by the Dutch as appertaining to their climate, do not at all exist in our's. The great ascendency which Holland has ever held in the culture of Bulbous Flowers, is the result of its soil, which is of peculiar formation, being a combination of marine sand made fresh by cultivation and bog mould; the proper means, therefore, to succeed equally in their culture, is to form a soil as near as possible of the same component parts, which is by no means a difficulty task. And, in fact, after all that has been said and written on the particular cultivation of Bulbous Roots, we often see the finest flowers in gardens where little or no attention is paid to them; and, perhaps, there is no class of plants which affords us so many delights, and so richly repays us for each little care bestowed on them.

The collections of Bulbous Flowers has been so greatly extended within these several years past, by a careful and scrutinizing selec-

tion of the most exquisite flowers of every country at all celebrated in their cultivation, that although some few collections in Europe may exceed this in the number of varieties, still it is believed few or none surpass it in the selection of the most choice aud intrinsic flowers; and prices have been paid in many cases altogether unwarranted by the demand this country has yet afforded, but with the expectation that the increasing botanic taste evinced throughout our country, would also in time devote to this class of plants the attention which it merits. It may be well to remark, that the Bulbs which are frequently sent out on consignment to this country from Holland, and sold at our auctions, are the mere refuse, and such as are held in no esteem, either by amateurs or connoisseurs, and no idea can be formed by them of the beauty of the more estimable kinds; and it is to be regretted that our citizens should have been so often duped in their purchases of these roots, under the imposition of high sounding names.

ADDITIONS.

HARDY TREES AND SHRUBS.

Male Osage Orange	$ 5	Berberis aquifolium	$ 25
Female do. do.	5	Tartarian Mulberry	1

ROSES.

Scarlet Moss	$ 5	White Pompone	$ 3
Striped Moss	5	Rubifolia	1
Prolific Moss	5	Long's Arkansaw	5
Mossy Rose de Meaux	5		

And above 200 others not yet increased.

STRAWBERRIES.

Each $ 1 *for two plants.*

TO THE PUBLIC.

The Proprietor has to announce to the public that he is at present engaged in preparing for the press a work to be entitled "American Horticulture," which will contain descriptions of all the varieties of fruits hitherto introduced from foreign climes, as well as all such as have originated or are indigenous to our own country. Also descriptions of all the Ornamental Trees, Shrubs, and Plants, either foreign or indigenous, that are most desirable to be cultivated in the different sections of the Union, and adapted to their different climates.

The Proprietor intends to touch largely on the culture of the Vine, Olive, Tanner's Sumack, Liquorice, Madder, and such other productions, the cultivation of which is calculated to render our country independent of foreign supplies.

The terms at which this work will be issued will be $ 5, and it is intended to put it to press as soon as one thousand subscribers are obtained; the names of subscribers can be forwarded to the Proprietor, or be given to the different Agents of the Establishment throughout the Union.

CONCLUSION.

Strangers who may wish to visit the Garden at the periods at which particular flowers may be seen in perfection, are informed that the Hyacinths are in perfection from the 1st to the 25th of April—Tulips from the 1st to the 15th of May—Roses from the 1st to the 15th of June—Pæonies during same period—Carnation Pinks from the 1st to the 15th of July—Dahlias from August to October —but among such a multitude of Plants from every region, there is at all times a great variety in flower, which are calculated to interest both the amateur and connoisseur.
