## **EXECUTIVE SUMMARY**

EnergySolutions (ES) and its partner, the Vitreous State Laboratory (VSL) of The Catholic University of America (CUA), are to provide engineering and technical services support to Savannah River Remediation, LLC (SRR) for ongoing operation of the Defense Waste Processing Facility (DWPF) flowsheet as well as for modifications to improve overall plant performance. SRR has requested that the glass formulation team of Savannah River National Laboratory (SRNL) and ES-VSL develop a technical basis that validates the current Product Composition Control System models for use during the processing of the coupled flowsheet or that leads to the refinements of or modifications to the models that are needed so that they may be used during the processing of the coupled flowsheet. SRNL has developed a matrix of test glasses that are to be batched and fabricated by ES-VSL as part of this effort. This document provides two analytical plans for use by ES-VSL: one plan is to guide the measurement of the chemical composition of the study glasses while the second is to guide the measurement of the durability of the study glasses based upon the results of testing by ASTM's Product Consistency Test (PCT) Method A.

## 1.0 Introduction

EnergySolutions (ES) and its partner, the Vitreous State Laboratory (VSL) of The Catholic University of America (CUA), are providing engineering and technical services support to Savannah River Remediation, LLC (SRR) for ongoing operation of the Defense Waste Processing Facility (DWPF) flowsheet as well as for modifications to improve overall plant performance. SRR has issued scopes of work to both the Savannah River National Laboratory (SRNL) and ES-VSL for glass formulation activities to support the integration of the Salt Waste Processing Facility (SWPF) into the DWPF flowsheet. Specifically, SRR has requested that the glass formulation team of SRNL and ES-VSL develop a technical basis that validates the current Product Composition Control System (PCCS) models for use during the processing of the coupled flowsheet or that leads to the refinements of or modifications to the models that are needed so that they may be used during the processing of the coupled flowsheet.

Peeler, Edwards, and Jantzen (2014a) issued a Task Technical and Quality Assurance Plan (TTQAP) that addressed SRNL's work scope to be performed in support of this task. The TTQAP was issued in response to the SRR Task Technical Request (Holtzscheiter (2014a)). SRNL's initial focus was an investigation into the compositional region for the DWPF glass waste-form anticipated by the integration of SWPF into the DWPF flowsheet. Under guidance from SRR (Fellinger, Holtzscheiter, and Shah (2014)), SRNL modified the projections for future sludge-only batches from SRR's Systems Plan Revision 19 (Chew and Hamm (2014)) to reflect coupled operations at DWPF and developed candidate frit compositions that would support the processing of these coupled projections in a manner that would meet SRR's operational goals as described in the guidance document. The results from this investigation were summarized by Peeler, Edwards, and Jantzen (2014b) and used to develop the glass waste-form compositional region of interest for this study (Peeler and Edwards (2014a)). From these efforts, Peeler and Edwards (2014b) developed a test matrix of 50 glass compositions that is to serve as the basis for the completion of the activities associated with this task.

SRR's Statement of Work (SOW) for ES-VSL (Holtzscheiter (2014b)) covers several activities that ES-VSL is to complete including:

- ◆ ES-VSL is to batch and fabricate the study glasses.
- ◆ ES-VSL is to measure the chemical compositions of these study glasses in accordance with an analytical plan, which is to be provided by SRNL.
- ◆ ES-VSL is to conduct a DWPF centerline canister cooled heat treatment for each of the study glasses in addition to the quenched version for each glass.
- ◆ ES-VSL is to subject samples of both heat treatments of each study glass to the ASTM Product Consistency Test (PCT) Method A (ASTM C1285 (2014)) for durability testing. The solutions resulting from this testing are to be subjected to chemical analyses by ES-VSL. These activities are to be conducted in accordance with an analytical plan, which is to be provided by SRNL.
- ◆ ES-VSL is to measure the liquidus temperature and viscosity for each study glass. No analytical plans are needed to support these measurements.

The purpose of this technical report is to provide the two analytical plans supporting these activities. Section 2 provides the description and background for the plan supporting the measurement of the chemical compositions of the study glasses. Appendix A repeats the portions of this chemical composition plan that may be supplied to the laboratory technicians and other appropriate staff to help in the completion of these measurements. Section 3 provides the description and background for the plan supporting the measurement of the solutions resulting from the PCT evaluations of the study glasses. Appendix B repeats the portions of the PCT plan that may be supplied to the laboratory technicians and other appropriate staff to help in the completion of the measurement of the PCTs.

The measurements generated by VSL are to be provided to SRR and SRNL for data reduction and evaluation. The results along with the other property measurements (i.e., liquidus temperature and viscosity) are to be incorporated into a final report by ES-VSL as a deliverable to SRR and SRNL in support of the SWPF gap analysis at DWPF.

## 2.0 Analytical Plan for the Measurement of Glass Compositions

The analytical plan needed by ES-VSL to support the measurement of the chemical compositions of the study glasses is outlined in the sub-sections that follow. The plan covers fifty (50) glasses containing thorium oxide and depleted uranium oxide that were identified by SRNL (Peeler and Edwards (2014b)).

### 2.1 Naming Conventions for Study Glasses and Prepared Samples

To provide a level of separation between the targeted compositions of the study glasses and the measurements of the study glasses during the analytical process, the naming convention provided in Table 2-1 is to be used to establish the identifiers for the samples that are to be submitted for laboratory analysis.

**Table 2-1. VSL Identifiers (IDs) for the Study Glasses Linked to the Sample IDs.**

### 2.2 Sample Preparation for Chemical Composition Analyses

Two methods are to be used to conduct the measurement of the chemical compositions of the study glasses: X-ray fluorescence spectroscopy (XRF) and Direct Coupled Plasma Atomic Emission Spectroscopy (DCP). Each of the study glasses is to be prepared by VSL in duplicate for each of these two measurement methods. The preparation of a single study glass for XRF analysis involves grinding a sample of the glass to less than 200 mesh and sealing each of two samples of the resultant glass in a different vial in sufficient quantities for subsequent XRF analysis. A labeling scheme for these vials that are to be submitted for XRF is provided in Table 2-2. The groupings and sequencing of these glasses that are indicated in this table also guide the glass fabrication process in that the glasses must be batched and melted before the activities of Table 2-2 may be pursued. Thus, the study glasses are to be batched and fabricated in the order as indicated by Table 2-2.

In addition to the grinding and sieving steps used to prepare samples for XRF, the preparation of samples for DCP analysis involves a chemical dissolution step. Thus, once a sample of a study glass has been ground to less than 200 mesh, two samples of the ground glass are to be prepared for subsequent XRF analysis, and, in addition an adequate quantity (to be determined by VSL) of the ground glass is to be placed in a separate vial for subsequent duplicate preparation for analysis by DCP. That is, duplicate samples from each of the vials are to be subjected to microwave-assisted total acid dissolution in Teflon vessels according to VSL standard operating procedures. Typically, a mixture of concentrated HF:HNO<sub>3</sub> is used to conduct the digestions with each digestion leading to a 50 mL solution. The resulting solutions are further diluted to 200 mL before DCP analysis. The 200 mL solutions are to be labeled as indicated in Table 2-3. The groupings of Table 2-3 are established in a manner that indicates that all of the batching and preliminary preparations (i.e., grinding) of the glasses are to be completed before the dissolution activities of Table 2-3 are initiated. Each block of Table 2-3 represents a microwave batch and the sequence provides an order for sample weighing.

In addition to the study glasses, a standard reference glass (to be selected by VSL) is to be prepared once for repeated analysis by XRF (see Section 2.3.1), and similarly, samples of this standard glass are to be prepared (i.e., dissolved for DCP analysis) to provide sufficient quantities to allow aliquots of the resulting solutions to be submitted for DCP analysis along with the prepared samples of the study glasses (see Section 2.3.2). It is anticipated that two or more preparations of the standard glass (Std-dcp) may be needed and, thus, one has been included in each of the preparation blocks of Table 2-3. If aliquots of more than one dissolution of the Std-dcp standard are needed to support the DCP analyses of Section 2.3.2, this should be noted as part of the information provided to SRNL along with the reported measurements.

### 2.3 Measurement of Chemical Compositions

Once samples of the study glasses and standard glass have been prepared they are to be submitted for chemical analysis by one of the two methods: XRF or DCP. The resulting measurements are to be provided to SRNL in elemental weight percent. A measurement below its detection limit should be indicated in this table by a less than sign (“<”) followed by the detection limit.

#### 2.3.1 Composition Measurement by XRF

Measurements for the following elements of interest, including elements that are minor components and whose concentrations may be below detection, are to be acquired by VSL using XRF: aluminum (Al), barium (Ba), calcium (Ca), cerium (Ce), cobalt (Co), chromium (Cr), cesium (Cs), copper (Cu), iron (Fe), potassium (K), lanthanum (La), magnesium (Mg), manganese (Mn), sodium (Na), nickel (Ni), lead (Pb), sulfur (S), silicon (Si), thorium (Th), titanium (Ti), uranium (U), zinc (Zn), and zirconium (Zr) concentrations. Once again, it should be noted that some of the elements listed above are minor components of the study glasses and may be below the detection limits of the analytical procedure. It should also be noted that this is a complete list of elements of interest for this glass study with the exception of boron (B) and lithium (Li); the measurement of these elements is addressed in the next section.

Blocking and randomizing the glass samples of Table 2-2 that are to be submitted for XRF measurement are primary concerns in the development of the analytical plan. It is anticipated that the day-to-day

variations of the XRF instrumentation may be a minor source of uncertainty for the analytical procedures used to determine the elemental concentrations for the submitted glass samples. However, to provide the data necessary to confirm this, the duplicate samples of each of the study glasses are to be analyzed by XRF on one day and then the pair of samples is to be analyzed on a subsequent day. A randomized plan that incorporates this approach in measuring the elemental concentrations of the glass samples prepared for XRF analysis is provided in Table 2-4. A PANalytical Axios mAX-Advanced or other equivalent wavelength dispersive XRF spectrometer is to be used for this purpose. The spectrometer is calibrated over a range of glass compositions using standard reference materials traceable to the National Institute of Standards and Technology (NIST), as well as waste glasses including the Argonne National Laboratory – Low Activity Reference Material (ANL-LRM), the Defense Waste Processing Facility – Environmental Assessment (DWPF-EA) glass, and Waste Treatment Plant (WTP) High-Level Waste (HLW) and Low-Activity Waste (LAW) glasses. A single sample of a reference glass, that is to be selected by VSL to be a matrix-match for this study and that is to be labeled as “Std-xrf”, is to be submitted repeatedly for measurement along with the samples of the study glasses as indicated in Table 2-4. The “known” composition of this reference glass is to be provided to SRNL along with the measured compositions from Table 2-4. These compositions are to be provided to SRNL as weight percent (wt%) elemental concentrations.

The sample identifiers in Table 2-4 have been modified to provide a labeling scheme for the measurements that are to be generated by these XRF determinations. Specifically, a suffix has been added to the label for the sample of the standard glass, Std-xrf, to indicate the XRF block (i.e., a 1 through 7), the measurement set (i.e., 1 (first) or 2 (second)), and its position (i.e., 1, 2, or 3) in the set. Finally, a suffix has been added to the sample identifier for the study glasses that indicates the measurement set (i.e., a 1 or 2).

### 2.3.2 Composition Measurement by DCP

The samples prepared for chemical analysis by DCP are to be measured for their boron and lithium content. Each of the duplicate preparations of each study glass is to be measured twice by DCP, with a re-calibration of the instrument being performed between the two measurements. The groupings and sequencing of these samples are provided in Table 2-5. To repeat, each column of this table indicates a different calibration of the DCP instrumentation. In addition, the order of the samples in a column is the sequence in which the samples should be measured by DCP. Also, note the addition of aliquots of the prepared samples of the reference glass, Std-dcp, to these DCP analytical blocks. The “known” composition of this reference glass (anticipated to be the same standard as used for the XRF analyses) is

to be provided to SRNL along with the measured compositions from Table 2-5. These compositions are to be provided as weight percent (wt%) elemental concentrations.

The sample identifiers in Table 2-5 have been modified to provide a labeling scheme for the measurements that are to be generated by these DCP determinations. Specifically, a suffix has been added to the label for the standard, Std-dcp, to indicate the DCP block (i.e., 1 through 7) and the calibration set (i.e., 1 (first) or 2 (second)). Finally, a suffix has been added to the sample identifier that indicates the calibration set (i.e., a 1 or 2).

**Table 2-5. DCP Analytical Blocks and Sequencing along with the Measurement Identifiers**

Appendix A repeats the critical portions and tables supporting the laboratory’s activities associated with the chemical composition analysis and reporting. The appendix is intended to provide a “detachable” work plan that may be provided to laboratory technicians.

### 3.0 Analytical Plan for the Measurement of PCT Solutions

A primary property of interest for the glasses of this study is durability as determined by the PCT, which is defined in ASTM C-1285 (latest revision). As stated above, the study glasses are to be subjected to two heat treatments. During their initial fabrication, the glasses are to be quenched. In a subsequent step, they are to be heat treated to simulate cooling along the centerline of a DWPF-type canister. This cooling

schedule is referred to as the centerline canister cooling (ccc) curve. Both heat treatments of each study glass will be subjected to the PCT. Comparisons between the durabilities of the resulting glasses will provide insight into the effects of thermal history on the product performance for these glasses.

Due to the large number of PCTs that are to be performed as part of this study, several oven runs are to be conducted with the grouping of study glasses in each of these runs detailed in this section. In addition to the study glasses, each oven run is to include triplicate PCTs of the Approved Reference Material – One (ARM-1) glass and triplicate PCTs of the EA glass. Two reagent blank samples are also to be included in each oven run. Each oven run is to contain 32 vessels with 8 vessels being needed for the standard and blank solutions. That leaves 24 vessels to support the study glasses in each oven run. With 6 vessels needed for a given study glass (3 for the quenched version and 3 for the ccc version), 4 study glasses can be included in each oven run. Thus, 13 oven runs are to be conducted to cover all of the PCTs needed to support this study. The activities involved in the completion of each oven run include labeling and grouping of the PCT solutions and of the solutions of the standards. These solutions are then to be grouped and ordered for analysis by Inductively Coupled Plasma – Atomic Emission Spectroscopy (ICP) or DCP. While the primary interest of these analyses is the measured concentrations of boron (B), lithium (Li), sodium (Na), and silicon (Si), the measurements of other elements (e.g., aluminum, iron, thorium, uranium, etc.) may also be recorded by VSL in order to provide a more complete set of results for these analyses. The results are to be reported to SRNL in parts per million (ppm). A measurement below its detection limit should be indicated in this table by a less than sign (“<”) followed by the detection limit.

### 3.1 Grouping of Glasses for Oven Runs

Table 3-1 presents the identifying codes, GAP-pct-001 through GAP-pct-404, that are to be used to label the individual solutions for each of the 13 oven runs that are required to complete these PCTs. Labels are provided for the solutions of the study glasses and of the standards (EA, ARM-1, and blanks). These codes provide a naming convention that is to be established by the VSL technicians conducting the PCT oven runs and then used by the laboratory technicians conducting the ICP or DCP analyses.

### 3.2 Measurement of the PCT Solutions

A multi-element solution standard (denoted by “std-ij” where i = A, B, C, ..., U represents one of the twenty-one block letters and j = 1, 2, and 3 represents the position in the block) is to be added at the beginning, middle, and end of each of the nine ICP or DCP blocks by the VSL laboratory technicians. VSL is to provide SRNL the reference values in ppm for the elemental concentrations of the multi-element standard. The measurements of the standard may be useful in checking for bias in the concentration measurements arising from the ICP or DCP calibrations.

As the analyses are conducted by VSL, each sample group or block of Table 3-2 requires a different calibration of the ICP or DCP instrumentation. Each of the solution samples of Table 3-2 is to be analyzed only once for each of the elements of interest to VSL. However, the following elements are to be provided to SRNL for further evaluation: boron (B), lithium (Li), sodium (Na), and silicon (Si) concentrations. The measurements provided to SRNL are to be reported in ppm after accounting for all dilutions and other adjustments conducted during the measurement process.

**Table 3-2. ICP or DCP Calibration Blocks for the Leachate Measurements for the PCTs<sup>f</sup>**

Appendix B repeats the critical portions and tables supporting the laboratory’s activities in determining the PCT results and reporting the data to SRNL. The appendix is intended to provide a “detachable” work plan that may be provided to laboratory technicians.

#### 4.0 Quality Assurance

Requirements for performing reviews of technical reports and the extent of review are established in manual E7 2.60. SRNL documents the extent and type of review using the SRNL Technical Report Design Checklist contained in WSRC-IM-2002-00011, Rev. 2.

#### 5.0 Summary

SRR has issued scopes of work to both the SRNL and ES-VSL for glass formulation activities to support the integration of the SWPF into the DWPF flowsheet. Specifically, SRR has requested that the glass formulation team of SRNL and ES-VSL develop a technical basis that validates the current PCCS models for use during the processing of the coupled flowsheet or that leads to the refinements of or modifications to the models that are needed so that they may be used during the processing of the coupled flowsheet. SRNL has developed a matrix of test glasses that are to be batched and fabricated by ES-VSL as part of this effort. This document provides two analytical plans for use by ES-VSL: one plan is to guide the measurement of the chemical composition of the study glasses while the second is to guide the measurement of the durability of the study glasses based upon their PCT responses.

#### 6.0 Path Forward

The measurements generated by VSL are to be provided to SRR and SRNL for data reduction and evaluation. The results along with the other property measurements (i.e., liquidus temperature and viscosity) are to be incorporated into a final report by ES-VSL as a deliverable to SRR and SRNL in support of the SWPF gap analysis at DWPF.

<sup>f</sup> Note that the PCT solutions from the final (13<sup>th</sup>) oven run support the final set of 3 blocks: S-U.

## Appendix A. Sample Preparation and Measurement of Glass Chemical Compositions<sup>f</sup>

Measurements for the following elements of interest, including elements that are minor components and whose concentrations are expected to be below detection, are to be acquired by VSL using X-ray fluorescence spectroscopy (XRF): aluminum (Al), barium (Ba), calcium (Ca), cerium (Ce), cobalt (Co), chromium (Cr), cesium (Cs), copper (Cu), iron (Fe), potassium (K), lanthanum (La), magnesium (Mg), manganese (Mn), sodium (Na), nickel (Ni), lead (Pb), sulfur (S), silicon (Si), thorium (Th), titanium (Ti), uranium (U), zinc (Zn), and zirconium (Zr) concentrations. Once again, it should be noted that some of the elements listed above are minor components of the study glasses and may be below the detection limits of the analytical procedure.

Also, a single sample of a reference glass, that is to be selected by VSL to be a matrix-match for this study and that is to be labeled as “Std-xrf”, is to be submitted repeatedly for measurement along with the samples of the study glasses as indicated in Table A-1. These compositions are to be provided to SRNL as weight percent (wt%) elemental concentrations. Table A-2 provides a template for use by VSL in reporting these results. A value below its detection limit should be indicated in this table by a less than sign (“<”) followed by the detection limit.

Duplicate samples of each of the study glass vials are to be subjected to microwave-assisted total acid dissolution in Teflon vessels according to VSL standard operating procedures. Typically, a mixture of concentrated HF:HNO<sub>3</sub> is used to conduct the digestions with each digestion leading to a 50 ml solution. The resulting solutions are further diluted to 200 ml before DCP analysis. The 200 ml solutions are to be labeled as indicated in Table A-3. The groupings of Table A-3 are established in a manner that indicates that all of the batching and preliminary preparations (i.e., grinding) of the glasses are to be completed before the dissolution activities of Table A-3 are initiated. Each block of Table A-3 represents a microwave batch and the sequence provides an order for sample weighing. In addition to the study glasses, a sample of the standard reference glass selected by VSL to support this study is to be similarly prepared in a large enough quantity to allow aliquots of the resulting solution to be submitted for DCP analysis along with the prepared samples of the study glasses (see Table A-4). This standard glass (Std-dcp) has been included in each of the preparation blocks of Table A-3.

The samples prepared for chemical analysis by DCP are to be measured for their boron and lithium content. Each of the duplicate preparations of each study glass is to be measured twice by DCP, with a re-calibration of the instrument being performed between the two measurements. The groupings and sequencing of these samples is provided in Table A-4. To repeat, each column of this table indicates a different calibration of the DCP instrumentation. In addition, the order of the samples in a column is the sequence in which the samples should be measured by DCP. Also, note the addition of aliquots of the prepared reference glass, Std-dcp, to these DCP analytical blocks. The “known” composition of this reference glass is to be provided to SRNL along with the measured compositions from Table A-4. These compositions are to be provided as weight percent (wt%) elemental concentrations.

## Appendix B. Measurement of PCT Solutions<sup>f</sup>

The PCT solutions are to be measured by Inductively Coupled Plasma – Atomic Emission Spectroscopy (ICP) or by DCP. A multi-element solution standard (denoted by “std-ij” where i = A, B, C, ..., U represents one of the 21 block letters and j = 1, 2, and 3 represents the position in the block) is to be added at the beginning, middle, and end of each of the twenty-one ICP or DCP blocks by the VSL laboratory technicians. As the analyses are conducted by VSL, each sample group or block of Table B-1 requires a different calibration of the ICP or DCP instrumentation. Each of the solution samples of Table B-1 is to be analyzed by VSL only once for each of the elements of interest to VSL. However, the following elements are to be provided to SRNL for further evaluation: boron (B), lithium (Li), sodium (Na), and silicon (Si) concentrations. The measurements provided to SRNL are to be reported in parts per million (ppm) after accounting for all dilutions and other adjustments conducted during the measurement process.

---

<sup>f</sup> Copies of this appendix are to be provided to the laboratory technicians at VSL who are to conduct ICP or DCP analyses of the PCT solutions.

**Table B-1. ICP or DCP Calibration Blocks for the Leachate Measurements for the PCTs**

Table B-2 provides a template for use by VSL in reporting these results. A value below its detection limit should be indicated in this table by a less than sign (“<”) followed by the detection limit.

**Table B-2. Reporting Template for the Leachate Measurements for the PCTs**
