Abstract

Background: *Stemona tuberosa* has long been used in Korean and Chinese medicine to ameliorate various lung diseases such as pneumonia and bronchitis. However, it has not yet been proven that *Stemona tuberosa* has positive effects on lung inflammation.

Methods: *Stemona tuberosa* extract (ST) was orally administered to C57BL/6 mice 2 hr before exposure to CS for 2 weeks. Twenty-four hours after the last CS exposure, mice were sacrificed to investigate the changes in the expression of cytokines such as tumor necrosis factor- α (TNF- α) and interleukin-6 (IL-6), chemokines such as keratinocyte-derived chemokine (KC) and inflammatory cells such as macrophages, neutrophils, and lymphocytes from bronchoalveolar lavage fluid (BALF). Furthermore, we compared the effect of ST on lung tissue morphology between the fresh air, CS exposure, and ST treatment groups.

Results: ST significantly decreased the numbers of total cells, macrophages, neutrophils, and lymphocytes in the BALF of mice that were exposed to CS. Additionally, ST reduced the levels of cytokines (TNF- α , IL-6) and the tested chemokine (KC) in BALF, as measured by enzyme-linked immunosorbent assay (ELISA). We also estimated the mean alveolar airspace (MAA) via morphometric analysis of lung tissues stained with hematoxylin and eosin (H&E). We found that ST inhibited the alveolar airspace enlargement induced by CS exposure. Furthermore, we observed that the lung tissues of mice treated with ST showed ameliorated epithelial hyperplasia of the bronchioles compared with those of mice exposed only to CS.

Conclusions: These results indicate that *Stemona tuberosa* has significant effects on lung inflammation in a subacute CS-induced mouse model. According to these outcomes, *Stemona tuberosa* may represent a novel therapeutic herb for the treatment of lung diseases including COPD.

Keywords: CS, *Stemona tuberosa*, BALF, COPD, TNF- α , IL-6

Background

Cigarette smoke (CS) comprises more than 4,500 compounds, including human carcinogens and many toxins such as nicotine, carbon monoxide [1]. CS, which is one of the risk factors of chronic obstructive pulmonary disease (COPD), increases various respiratory symptoms resulting from functional lung abnormalities such as a

reduced forced expiratory volume in 1 sec (FEV1) [2]. CS induces lung inflammation through different types of mechanisms, including reduced fibroblast proliferation and migration, and genetic mutations in the lung [3-6]. Furthermore, various types of inflammatory cells, cytokines and chemokines are widely studied with regard to the activation of acute or chronic inflammation in the lungs, which may be important factors for understanding the mechanisms of lung inflammation and developing new approaches to treat lung diseases including COPD [7].

Full list of author information is available at the end of the article

When exposed to CS, cytokines such as tumor necrosis factor- α (TNF- α) and interleukin-6 (IL-6) and the chemokine, keratinocyte-derived chemokine (KC) which is a neutrophil chemoattractant, were found to be elevated in the bronchoalveolar lavage fluid (BALF) of mice [8]. Inflammatory cells including macrophages, neutrophils, and lymphocytes also accumulated in BALF. These inflammatory cells release inflammatory substances such as enzymes that destroy collagen and elastin and stimulate mucosal secretions in the lung tissues, resulting in lung diseases like emphysema, chronic bronchitis, and COPD [1].

Meanwhile, COPD is a major public health problem worldwide. By definition, COPD is characterized by continued airflow limitation that is progressive and is associated with an increasing chronic inflammatory response in the airways and the lung to hazardous particles or gases, including CS. COPD has a higher risk of mortality than other diseases such as angina, respiratory infection, fractures, myocardial infarction, and osteoporosis [9]. In 2020, COPD is expected to rank fifth in terms of the burden of disease and will likely rank third as a cause of mortality [10].

Roflumilast, a common therapy for lung diseases such as asthma and COPD, has been shown to inhibit the increased secretion of cytokines such as TNF- α and interferon- γ (INF- γ), and chemokines such as CCL2, CCL4, CXCL1, CXCL8, and CXCL10 in experimental studies of lung inflammation [11-13]. Roflumilast is generally used for treatment of COPD patients with reliable evidence of clinical trials [14,15]. Based on these results, roflumilast was used in our study as a positive control.

Stemona tuberosa has long been used as a therapeutic herb in Korean and Chinese medicine for the treatment of lung diseases. There have been some reports on the antifungal or antibacterial effects of *Stemona tuberosa* [16-18], however, there have been only a few studies on its inhibitory effects on lung inflammation. It has also been reported that *Stemona tuberosa* has a significant effect on components of the respiratory system such as the larynx and the lungs [19,20]. In this study, we investigated the effect of *Stemona tuberosa* on lung inflammation via a subacute CS-induced mouse model. We examined the therapeutic effects of ST in terms of both immunological changes such as decreased cytokines (TNF- α , IL-6) and chemokine (KC), and morphological changes in the lung microenvironment.

Methods

Animals

Groups of five six-week-old female C57BL/6 mice were purchased from Charles River Korea (Seoungnam, South Korea). All mice were kept under pathogen-free

conditions with air conditioning and a 12 hr light/dark cycle. In addition, all mice had free access to food and water during the experiments. This experimental study was approved by the Institutional Animal Care and Use Board of Kyung Hee University (KHUASP (SE)-12-015).

Preparation of *Stemona tuberosa* and phytochemical analysis

ST was purchased from Sun Ten (Sun Ten Pharmaceutical Co., Ltd. Taiwan). According to the manufacturer's procedure, water extraction of *Stemona tuberosa* was performed. At first, the *Stemona tuberosa* was water extracted at 100°C for 60 min. And then, the remains of the herbs and impurities were separated from the extracted liquid as a filtration separation process. The water extracts were then spray dried and corn starch was added as an excipient to stabilize the concentrated herbal products (final ratio of water extracts vs starch is 7:3, Batch No: 110410). After these procedures, the final product of *Stemona tuberosa* extract (ST) was produced in Sun Ten. ST was carefully measured to prepare the necessary weights for each treatment group and then dissolved in distilled water (DW) for 30 min at room temperature.

Stemona tuberosa extract (ST) is one of the herbal extracts in PM014, which are well-standardized herbal formula and has been investigated for treating lung diseases recently [21]. PM014 has been already approved for the Investigation New Drug (IND) application from Ministry of Food and Drug Safety, Republic of Korea (ID:20130030575) through quantitating standard materials by high-performance liquid chromatography (HPLC) analysis. Accordingly, ST can be considered as a standardized plant extract.

For the phytochemical analysis of ST, HPLC was performed. The ST was accurately weighed to 10.53 mg and then dissolved in 2 ml of methanol. The sample was treated with ultrasonic waves for 30 min, and the supernatant of the sample was then filtered through a 0.45- μ m syringe filter. For the quantitative analysis of ST, tuberos-tonine N, one of the known alkaloid constituents of ST, was isolated from the ethyl acetate extract of ST by repeated column chromatography. HPLC analysis were conducted using a Waters system (Waters Co., Milford, MA, USA) with a 2424 ELS detector and a 1525 binary HPLC pump. A Waters Millennium 32 System (Waters Co., Milford, MA, USA) was used for data acquisition and integration. The samples were analyzed by reverse phase (C18) HPLC analysis (Agilent prep-C18 Scalar, 4.6 \times 250 mm i.d., 5 μ m, flow rate: 0.5 ml/min) using a gradient solvent system of acetonitrile containing 0.05% triethylamine (A) and water (B) as follows: 40% A at 0–10 min, 40 \rightarrow 50% A at 10–20 min, 50% A at 20–40 min, 50 \rightarrow 40% A at 40–50 min and 40% A at 50–60 min. The drift

tube temperature for ELSD was set at 60°C, with 50 psi of pressure of the nebulizing nitrogen gas. The ELSD generates a signal in direct proportion to the quantity of the analyte present. Using this method, the concentration of tuberostemonine N in ST was calculated to be 0.3 mg/g (yield 0.03%) as described in (Figure 1).

High Performance Liquid Chromatography – electrospray tandem mass spectrometry (HPLC-ESI-MS) analysis

The HPLC (High performance liquid chromatography) system operated by Chromeleon (Thermo Fisher Scientific, USA) and consisted of Dionex model P680 HPLC pump, a ASI-100 Automated Sample injector and a UVD 340U. The Brownlee Analytical C18 column (4.6 × 250 mm, 5 μm) was selected for the analysis. The monitoring wavelength was set to 254 nm. The mobile phase was comprised of acetonitrile with triethylamine (0.1%, solvent A) and water (solvent B). All solvents were filtered through a 0.45 μm filter. The gradient program was 0–10 min, 40% of solvent A; 10–12 min, linear from 40 to 50% of solvent A; 12–28 min, 50% of solvent A; 28–30 min, linear from 50 to 40% of solvent A, at a flow rate of 0.6 mL per min. The injection volume was 10 μL.

AccuTOF® single-reflectron time-of-flight mass spectrometer was operated with Mass Center system version 1.3.7b (JEOL, USA) and was equipped with an ESI source (Electrospray ionization, JEOL, USA). In the positive ion mode, the atmospheric pressure interface potentials were typically set to the following values: orifice 1 = 80 V and

ring lens and orifice 2 = 10, 5 V, respectively. The ion guide potential and detector voltage were set to 2000 V and 2300 V, respectively. ESI parameters were set as follows: needle electrode = 2000 V, nitrogen gas was used as a nebulizer, desolvating and their flow rate were 1 and 3 L/min, desolvating chamber temperature = 250°C, orifice 1 temperature = 80°C. Mass scale calibration was accomplished with Yokudelna (Koyo Science Co., LTD., Japan) for accurate mass measurements and calculations of the elemental composition. MS acquisition was set with a scan range of m/z 50 to 1500.

A mouse model of subacute CS-induced lung inflammation and drug treatment

Female C57BL/6 mice were exposed to either fresh air (as a control group) or CS generated by 3R4F Kentucky Reference Cigarettes (University of Kentucky, Lexington, KY). As the subacute CS-induced lung inflammation mouse model used here was based on previous studies [22,23], mice were exposed over their entire bodies to the smoke of five cigarettes, four times per day with 30 min smoke-free intervals, on 6 days per week for 2 weeks. They were dosed with DW on days 0 and 1, and DW or ST on days 2 to 5 and 7 to 12 as described in (Figure 2). The mice were treated with 5 mg/kg dose of roflumilast (Santa Cruz Biotechnology, Inc., CA, USA) orally as a positive control on the same days as ST, and different doses of ST (50, 100, and 200 mg/kg) via oral injection 2 hr before exposure to CS. On day 13,

the mice were sacrificed to obtain BALF and lung tissues for confirming this mouse model is successful and analyzing the results.

Analysis of bronchoalveolar lavage fluid (BALF)

BALF was collected by the infusion and extraction of 1 ml of ice cold phosphate buffered saline (PBS). This procedure was repeated three times, and the lavages were pooled. The recovered BALF (70–80%) was centrifuged at 1,300 rpm for 10 min. The cell pellets were resuspended in 1 ml PBS and adhered to glass slides using cytocentrifugation. The total viable cell counts were determined in a hemocytometer using the trypan blue exclusion method. Differential counts of macrophages, neutrophils, and lymphocytes were determined on Diff-Quick-stained (Life Technologies, Auckland, New Zealand) cytospin smears of BALF samples (5×10^5 /200 μ l cells) from individual mice. BALF samples were then centrifuged and the supernatants were kept at -80°C . The results are expressed as the total cell number $\times 10^4$.

Assessment of protein, cytokines and chemokines in BALF using Enzyme-Linked Immunosorbent Assay (ELISA)

Protein concentrations were determined using a BCA kit (Pierce Biotechnology Inc., IL, USA). A total 25 μ l of the centrifuged BALF samples was placed into the microplate well, and then 200 μ l of the working reagent was added to the each well. After incubation at 37°C for 30 min, the optical density was measured at 590 nm in a microplate reader (SOFT max PRO, version 3.1 software, Sunnyvale, CA, USA). The concentrations of cytokines (TNF- α , IL-6) and the chemokine (KC) were measured with a quantitative sandwich enzyme-linked immunoassay kit (BD, San Diego, CA, USA) following the

manufacturer's instructions. Microtiter plates (96-well, Costar, Corning, NY, USA) were incubated overnight at 4°C with anti-mouse TNF- α , IL-6, and KC monoclonal antibodies in coating buffer. The wells were then washed with PBS containing 0.05% Tween-20 (Sigma-Aldrich Co., St. Louis, MO, USA) and blocked with 5% FBS and 1% BSA in PBS. Subsequently, each well was loaded with 100 μ l of BALF and incubated for 2 hr at room temperature. The wells were then incubated with peroxidase-labeled biotinylated anti-mouse TNF- α , IL-6, and KC monoclonal secondary antibodies in assay diluents for 1 h. Finally, the plates were treated with TMB substrate solution (KPL, San Diego, CA, USA) for 30 min, and the reaction was stopped by the addition TMB stop solution. Optical density was measured at 450 nm in a microplate reader (SOFT max PRO, version 3.1 software, Sunnyvale, CA, USA). The detection limits for the TNF- α , IL-6, and KC ELISAs were 1000 pg/ml each. The optical densities for TNF- α , IL-6, and KC were each divided by the total protein concentrations of the respective BALF samples for standardization purposes.

Histological examination of lung tissues

The lung tissues were removed from the mice, and the right, lower lobes of the lungs were removed for histological analysis. Four percent paraformaldehyde fixing solution was infused into the lungs. The specimens were dehydrated and embedded in paraffin. For histological examination, 4- μ m sections of embedded tissues were cut on a rotary microtome, after which they were placed on glass slides, deparaffinized, and stained sequentially with hematoxylin and eosin (H&E). Images of lung tissue sections stained with H&E were acquired with an Olympus BX51 microscope (Olympus, Tokyo, Japan) under $\times 200$ magnification. Five randomly selected sections of the slides, cross-sections of lung parenchyma, were captured, digitized and evaluated using Image Pro-Plus 5.1 software (Media Cybernetics, Inc., Silver Spring, MD, USA). Mean alveolar airspace (MAA), a quantitative assessment of lung structure, was determined from the sum of the alveolar airspace areas divided by the number of identified alveoli. The bronchial epithelium was observed with periodic acid Schiff (PAS)-stained sections.

Statistical analysis

Statistical analysis of the data was conducted using Prism 5 software (GraphPad Software Inc., Irvine, CA, USA). All values are presented as the means \pm S.E.M. (standard error of the mean). Differences between the means of the control and the treatment samples were determined by one-way ANOVA for multiple group comparisons followed by Newman-Keuls post hoc comparisons. In all cases, $p < 0.05$ was considered to be statistically significant.

Results

***Stemona tuberosa* extract (ST) inhibits the increase of inflammatory cells in BALF**

Stemona granule was analyzed using HPLC-ESI-MS for the analysis and identification of major components. As shown in Table 1, characteristic components of *Stemona* species including *stemona* alkaloids were identified by the comparison of their retention order and molecular weight with previous reports [24].

***Stemona tuberosa* extract (ST) inhibits the increase of inflammatory cells in BALF**

BALF was analyzed to evaluate how ST has a significant effect on lung inflammation in a subacute CS-induced mouse model. In previous studies, the number of total inflammatory cells was significantly increased when mice were exposed to CS for 2 weeks [23,25]. In our study, CS caused a significant increase in the number of total inflammatory cells compared with mice that were exposed to fresh air only (Figure 3). On the other hand, roflumilast and ST in all doses showed significant decrease in the number of total inflammatory cells in BALF. It is safe to say that ST has an inhibitory effect on the increase of inflammatory cells in BALF.

An analysis of differential BALF cell counts is also essential to examining the anti-inflammatory effect of ST (Figure 3). Macrophages, neutrophils, and lymphocytes are well known to infiltrate from the alveoli to the bronchoalveolar lavage in order to contribute to lung inflammation that results from CS exposure [26]. The group of mice exposed to CS (CS group) showed significant increases in the number of macrophages, neutrophils, and lymphocytes compared with group of mice that were exposed to fresh air only as a negative control (AIR group). Additionally, roflumilast and ST (50, 100, and 200 mg/kg) inhibited the increase of neutrophils and lymphocytes in BALF compared with the CS group. In detail, the number of macrophages was decreased to a lesser degree than that of neutrophils and lymphocytes. In the previous study, roflumilast did not show the remarkable inhibitory effect on increased macrophages in BALF [13]. ST had the tendency to decrease the number of macrophages in BALF, but this reduction did not surpass that

induced by roflumilast. ST also decreased the number of neutrophils to a similar degree as did roflumilast. However, ST surprisingly had a significant effect on decreasing the number of lymphocytes in a dose-dependent manner, and this effect was more significant than that of roflumilast.

***Stemona tuberosa* extract (ST) reduces the level of proinflammatory mediators in BALF**

ELISA was used to evaluate the differences in the expression of inflammatory mediators such as cytokines (TNF- α , IL-6) and the chemokine, KC, between the treatment groups. In previous studies, the secretion of TNF- α and IL-6 into the BALF was shown to be activated in response to CS via some types of inflammatory cells [27-29]. KC, a chemokine which is also called chemokine (C-X-C motif) ligand 1 and growth-related oncogene α , was found to be elevated in lung inflammation induced by CS [30,31]. In this study, we identified that the levels of both cytokines (TNF- α , IL-6) and KC were significantly elevated in the CS group compared to the AIR group (Figure 4).

Roflumilast, a positive control in this study, had inhibitory effects on the increased cytokine (TNF- α , IL-6) and chemokine (KC) secretion observed in our study (Figure 4). Specifically, the levels of TNF- α and IL-6 in the group of mice treated with roflumilast (ROFL group) were significantly decreased compared with levels in the CS group, but the level of KC only had the tendency to be decreased, as was observed in previous studies [32]. In addition, ST-treated mice showed significantly decreased levels of TNF- α and IL-6 in all treated doses to the same degree as that caused by roflumilast. These remarkable changes in cytokine and chemokine levels strongly demonstrate that ST reduces the level of proinflammatory mediators in BALF.

***Stemona tuberosa* extract (ST) disturbs the recruitment of neutrophils in lung tissues**

We previously found that CS induces an increase of neutrophils in BALF through the assessment of differential cell counts, as described in the Methods section. This recruitment could also be observed upon

Table 1 The observed and calculated mass numbers of LC/ESI-MS peaks of *Stemona* Radix granules

Peak No.	Rt (min)	Theoretical mass [M + H] ⁺	Observed mass [M + H] ⁺	Mass difference (mmu)	Identification

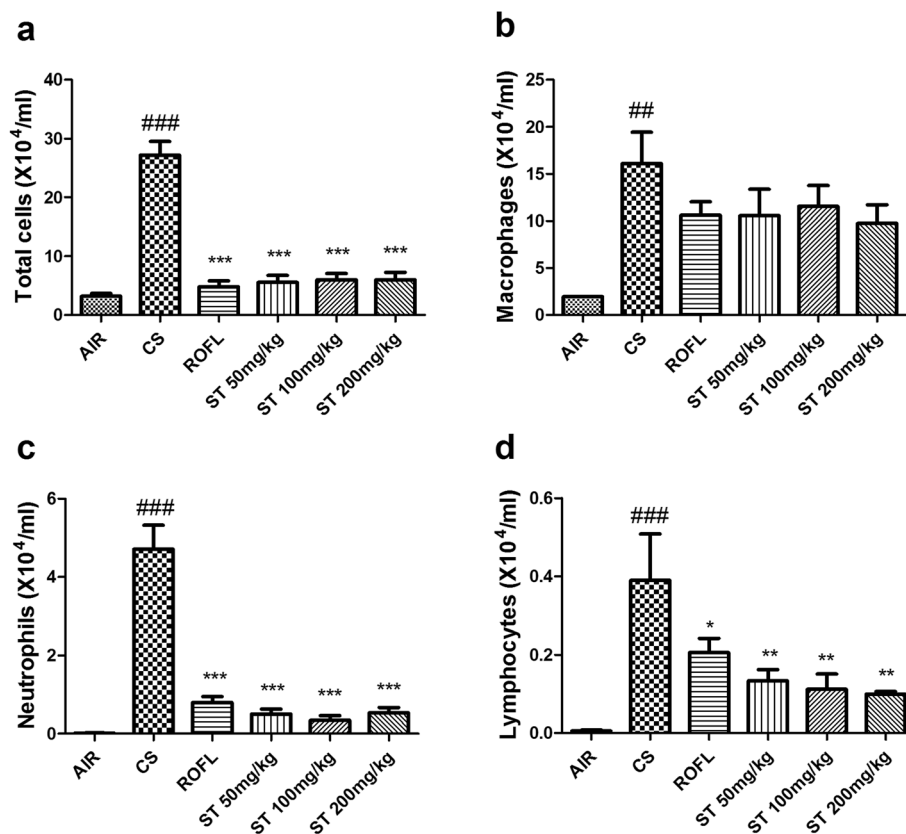

Figure 3 Total and differential cell counts in BALF. Exposure to cigarette smoke (CS) increased the numbers of total cells, macrophages, neutrophils, and lymphocytes in BALF. In addition, ST significantly reduced the numbers of these inflammatory cells in BALF to a similar degree as roflumilast. The numbers of cells in BALF were counted using a hemocytometer, and differential cell counts were performed on slides prepared by cytocentrifugation at 250 rpm for 3 min followed by Diff-Quick staining. **a)** Count of total cell number, **b)** Count of macrophages, **c)** Count of neutrophils, **d)** Count of lymphocytes. $n = 5$ in all groups. Data are shown as the mean \pm S.E.M. Statistical analyses were conducted by one-way ANOVA followed by Newman-Keuls Multiple Comparison test; ### $p < 0.001$, ## $p < 0.01$ vs. AIR, *** $p < 0.001$, ** $p < 0.01$, * $p < 0.05$ vs. CS.

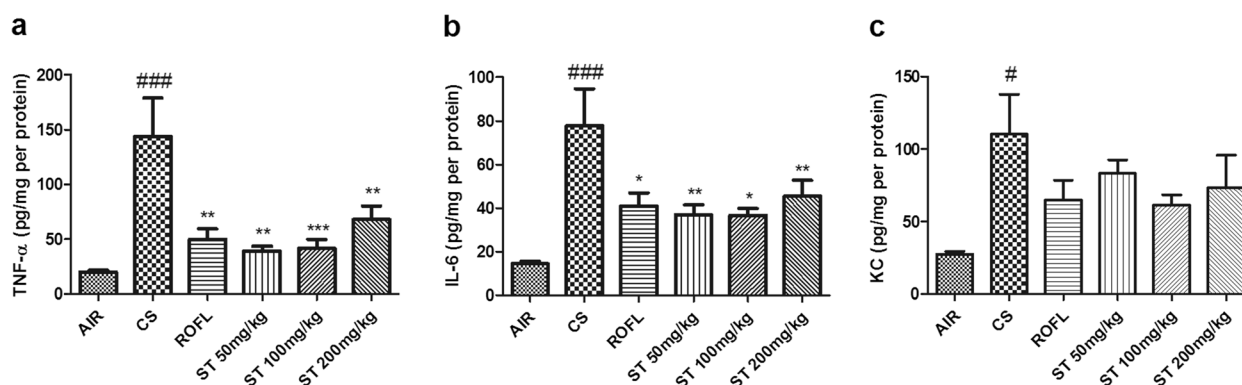

Figure 4 Measurement of TNF- α , IL-6, and KC levels in BALF by ELISA. BALF samples were collected as described in Figure 2. ST reduced the level of cytokines (TNF- α , IL-6) and chemokine (KC) when measured with a quantitative sandwich enzyme-linked immunoassay (ELISA). **a)** TNF- α , **b)** IL-6, **c)** KC. $n = 5$ in all groups. Data are shown as the mean \pm S.E.M. Statistical analyses were conducted by one-way ANOVA followed by Newman-Keuls Multiple Comparison test; ### $p < 0.001$, # $p < 0.05$ vs. AIR, *** $p < 0.001$, ** $p < 0.01$, * $p < 0.05$ vs. CS.

histological examination. Many researchers have reported that neutrophils accumulate in the tissue to induce the lung inflammation, a leading potential mechanism of alveolar destruction in emphysema [33-35]. The accumulation of neutrophils around the bronchioles of the small airways was shown in lung tissue sections stained with H&E. This accumulation was reported to result from the circulating neutrophils that had margined into the pulmonary circulation and adhered to endothelial cells in the alveolar wall before infiltrating into the alveolar space [36,37]. In this study, it was revealed that neutrophils located in the peribronchial airway were predominantly increased in the lung tissues of the CS group

compared to the AIR group (Figure 5A). Additionally, the lung morphology of mice treated with ST (50, 100, and 200 mg/kg) showed that ST disturbed the accumulation of neutrophils throughout the peribronchial airway when compared with that of mice that were only exposed to CS without any treatment. The morphological appearance of the ST group was similar to that of the ROFL group.

***Stemona tuberosa* extract (ST) decreases the airspace enlargement as observed by morphometric analysis**

Several investigations indicated that the exposure to CS significantly induced the destruction of the alveolar wall and airspace enlargement through lung inflammation,

Figure 5 Neutrophil recruitment and airspace enlargement in lung tissue. a) The right lower lobes of mice were dissected and stained with hematoxylin and eosin ($\times 200$ magnification). ST disturbed the neutrophil accumulation in the peribronchial airway. **b)** Mean alveolar airspace (MAA), a morphometrical analysis, was assessed using Image Pro-Plus 5.1 software as described in the Methods section. $n = 5$ in all groups. Data are shown as the mean \pm S.E.M. Statistical analyses were conducted by one-way ANOVA followed by Newman-Keuls Multiple Comparison test; ### $p < 0.001$ vs. AIR, *** $p < 0.001$ vs. CS.

oxidative stress and apoptosis [38-42]. We assessed the MAA in lung tissue sections stained with H&E via morphometric analysis, which is a quantitative assessment used to measure the changes of airspace enlargement [43,44]. Serious airspace enlargement in a subacute CS-induced mouse model due to lung inflammation and alveolar wall destruction could be identified in our study by comparing MAA levels between the AIR group and the CS group (Figure 5B). Meanwhile, the oral administration of roflumilast and all doses of ST significantly reduced the level of MAA. Specifically, the level of MAA in each ST group decreased a little more than that in the ROFL group, and ST had a dose-dependent effect on the prevention of alveolar airspace enlargement, based on this quantitative assessment.

Stemona tuberosa extract (ST) attenuates the epithelial hyperplasia of the bronchioles

Many research articles have described that CS-induced inflammatory cell infiltration, metaplasia of goblet cells, and fibrosis result in the increased thickness of the bronchial epithelium [22,45-48]. However, even though mice were exposed to CS chronically, the metaplasia of goblet cells in the bronchial epithelium was hardly found, but there were plentiful numbers of goblet cells in human and guinea pig when exposed to CS. Accordingly, some studies of the CS-induced lung inflammation mouse model have only investigated the epithelial hyperplasia of the bronchioles because of the difficulty in estimating the number of goblet cells in the bronchial epithelium of mice [49-51]. PAS stain method has been used to distinguish the epithelial thickness of bronchiole in other studies [22,52]. In this mouse model of subacute CS-induced lung inflammation, lung tissues of the CS group

stained with PAS showed the epithelial hyperplasia of the bronchioles, leading to the increased thickness of bronchial epithelium compared with the AIR group (Figure 6). The inhibition of epithelial hyperplasia of the bronchioles was also observed in PAS-stained lung tissues of the ST group, similar to those of the ROFL group. Morphologically, more than two epithelial cells were clustered and formed a thick layer of bronchial epithelium in that of the CS group, but there was only a single row of epithelial cells in the lung tissues of the ST group.

Discussion

For thousands of years many drugs including natural plants and chemical compounds have been investigated to find effective treatments for lung diseases such as bronchitis, asthma, and COPD. Particularly in Korean and Chinese medicine, traditional medical doctors have used therapeutic herbs to treat lung diseases according to their traditional medical reference books such as Huangdineijing and DonguiBogam. DonguiBogam was published by the royal physician Jun Heo in the Joseon Dynasty of Korea and designated as UNESCO's memory of the world register in 2009 [53]. Under the contemporary and social requirements, many researchers have made an effort to demonstrate the therapeutic effects of the herbs introduced in those literatures, and found some therapeutic herbs such as *Lilium lancifolium*, *Liriopsis tuber*, *Coscinium fenestratum*, and *Prunus armeniaca* have been proved to have an interesting effect on lung diseases [53-56]. ST has also shown promise as an alternative treatment for lung diseases [19,20].

To evaluate the degree of inhibition of lung inflammation, many researchers prefer the CS-induced mouse

Figure 6 Epithelial hyperplasia of the bronchioles. The right lower lobes of mice were dissected and stained with periodic acid Schiff (PAS) as described in the Methods section (×400 magnification). In the cigarette smoke (CS) group, there was a multi-layer of bronchial epithelium, whereas there was approximately a single layer of bronchial epithelium in the fresh air (AIR), roflumilast (ROFL), and ST groups.

model over other models due to the following advantages. This model is induced by the same insult as observed in humans and produces emphysema, airway remodeling, and physiological alterations similar to humans [51]. In our study, the effect of *Stemona tuberosa* on lung inflammation was investigated using a CS-induced mouse model, which is one of the models that is most similar to lung diseases including COPD. Two weeks of cigarette smoke exposure in this model was enough to induce alveolar wall destruction and airspace enlargement, based on previous studies [21,53-57].

CS, which nearly accounts for 80-90% of COPD cases in the United States, induces pathobiological processes in the respiratory system [58]. A plenty of results from other studies likely demonstrate that airspace enlargement and neutrophil accumulation around the peribronchial airway in our histologic analysis have a significant relationship with the increased macrophages and neutrophils found in BALF after CS exposure [59-63]. However, more detailed studies should be performed to identify whether the inhibitory effect of ST on lung inflammation involves these mechanisms.

In our research, we also investigated the changes in lymphocyte levels as well as those of macrophages and neutrophils because lymphocytes are another important factor in lung inflammation related to respiratory diseases such as asthma and COPD. In asthma, the CD4⁺ T cells, a type of lymphocyte, are the crucial mediators of a Th2 type immune response in the bronchial airway, whereas the CD8⁺ T cells are more important in COPD [64,65]. The greater the CS exposure, the larger the population of total T cells, including CD3⁺, CD4⁺, CD8⁺, and $\gamma\delta$ T cells in the alveolar wall, in the previous study. Of all these T cells, CD8⁺ T cells were the most predominant cell type found in bronchial airways in smokers with emphysema. These results suggested that CD8⁺ T cells induced structural cell apoptosis in the lung [66]. A recent study also demonstrated that CD3⁺ T cells could be another pathogenic cell in mice exposed to CS, leading to neutrophil accumulation, enhanced levels of cytokines and chemokines, structural cell apoptosis of the alveoli, and airspace enlargement [67]. In our research, the increased level of lymphocytes could also be associated with airspace enlargement observed via morphometric analysis. In conclusion, several types of lymphocytes such as CD3⁺, CD4⁺, and CD8⁺ T may be candidate targets of ST, which would explain the finding of decreased lymphocyte levels in BALF and reduced airspace enlargement in the ST groups, compared with those in the CS group.

In our research, we investigated the alteration of the cytokines (TNF- α , IL-6) and the chemokine (KC) in BALF by ELISA to assess the inhibitory effect of ST. These cytokines and the chemokine have been generally

used in CS-induced mouse model, especially for COPD in previous studies [21,68,69]. Some studies have reported that a variety of cytokines and chemokines in BALF are involved with the lung inflammation induced by CS and are also increased in COPD patients [70]. Previous studies reported that TNF- α overexpression can be observed in the lung tissue of normal mice exposed to CS, whereas TNF- α receptor knockout mice were protected from the severe inflammation caused by CS. Furthermore, increased TNF- α levels stimulated the MMP synthesis of alveolar macrophages, resulting in alveolar wall destruction and airspace enlargement [71,72]. Meanwhile, IL-6, a cytokine released by macrophages, lymphocytes, and endothelial cells, is another target to treat lung inflammation leading to COPD. IL-6 is also known to contribute to impaired endothelial cell function, which leads to enlarged alveolar airspaces [73,74]. ST could be a potential alternative to existing treatments that inhibit TNF- α and IL-6 because we have shown in this study that ST can attenuate TNF- α and IL-6 levels.

We investigated the effect of ST on lung inflammation through total cell counts, differential cell counts, changes in the level of the cytokines (TNF- α , IL-6) and the chemokine (KC) by ELISA, and the morphological analysis of lung tissues stained with H&E and PAS. Our goal is to identify a new therapeutic herb for lung diseases such as COPD based on other studies of the respiratory effects of ST [19]. The respiratory effects of ST, however, were demonstrated for symptoms such as antitussive and respiratory depressant effects, so our study tried to minutely examine the immunological changes associated with these effects. In summary, ST inhibited the increase of several inflammatory cells such as macrophages, neutrophils, and lymphocytes, and decreased the levels of proinflammatory cytokines such as TNF- α and IL-6 and the chemokine, KC. This immunological downregulation in lung tissue may lead to reduced alveolar wall destruction, airspace enlargement, and epithelial hyperplasia of the bronchioles, as demonstrated by morphological analysis and MAA measurements. Although inflammatory cells and mediators in BALF and MAA in lung tissue that we investigated were significantly reduced in all doses of ST treatment group rather than CS exposure group, we could not find the differences among the three doses of ST except dose-dependent decrease in the number of lymphocytes. Meanwhile, it is possible that 50 mg/kg of ST, the minimum dose in our study, already reached the maximal effect on lung inflammation in this model.

We could find a few limitations in this mice model to evaluate the effect of ST. First, we had a difficulty in finding the increased number of goblet cells or fibrotic changes in the bronchial epithelium of CS group. To evaluate the effect of ST with these characteristics, researchers should perform this experimental study with

other strains of mice, or guinea pig [51,75]. Secondly, this study was designed to examine the effects of CS exposure in regard to inflammation only. Recent studies, however, examine the effects of CS exposure in the aspect of DNA damage as well as inflammation [76]. Furthermore, one study researched the effect of a therapeutic herb, *Zataria multiflora*, on systemic inflammation of experimental animal model of COPD. They used biochemical parameters such as measurement of malondialdehyde and differential cell count in the blood sample [77]. According to these recent studies, other biomarkers that can evaluate the effect of ST on targeting the treatment of COPD should be performed for the further studies.

Previous studies have been conducted to discover the components of ST such as neotuberostemonine, tuberostemonine, croomine, and stemoninine, as well as their chemical structures, effects, and ethnopharmacological uses [20,24,78]. In one of these studies, tuberostemonine was proven to have an inhibitory effect on the neuromuscular junction [79]. Additionally, some *Stemona* species other than ST have been continuously used as therapeutic agents in Korean and Chinese medicine. For instance, *Stemona japonica* and its alkaloids have insecticidal and antifungal effects [18,80]. *Stemona sessilifolia* and its alkaloids also have acetylcholinesterase inhibitory activity as well as antibacterial and antitussive effects [17,81,82]. To extend a helping hand to patients with lung diseases such as COPD, the effects of ST should be compared with these similar species through the pathobiological investigation of both experimental and clinical trials. Also, further researches should be performed to discover which phytoconstituents of ST have crucial inhibitory effect on lung inflammation. With the help of additional studies, ST may represent a potential alternative for existing drugs, such as roflumilast, that are used to treat lung diseases and have some side effects. Roflumilast, an oral phosphodiesterase-4 (PDE) inhibitor, can improve lung diseases such as COPD, but side effects have been reported. The most common side effects include diarrhea, nausea, and headache [83]. ST could be a good therapeutic agent for lung diseases and may even be a better treatment than roflumilast. However, it is necessary that the elaborate mechanisms of ST be precisely discovered by additional experiments, and it should be produced in farms of good agricultural practice (GAP) and pharmaceutical companies of good manufacturing practice (GMP) [19]. In conclusion, based on our results that ST has significant inhibitory effects in a mouse model of subacute CS-induced lung inflammation, more studies should be performed to determine the critical targets of ST, whether ST has any side effects, and how ST can be manufactured with the best effectiveness and efficacy for the purpose of its pharmacological development and clinical use.

Conclusions

We found the significant changes of lung inflammation in a subacute cigarette smoke-induced mouse model. With this mouse model, we discovered that ST treatment decreased a variety of inflammatory cells of the lung such as macrophages, neutrophils, and lymphocytes and reduced the level of cytokines (TNF- α , IL-6) and a chemokine (KC) induced by CS exposure. It also attenuated the airspace enlargement and epithelial hyperplasia of bronchioles in lung tissues obtained from the mouse model of subacute CS-induced lung inflammation. These results strongly suggest that ST may be a new valuable therapeutic agent for the treatment of lung diseases such as COPD.
