Abstract

In this article, we investigate a split feasibility problem via a regularization iterative algorithm. Strong convergence theorems of solutions for the split feasibility are established in the framework of Hilbert spaces. We also apply our main results to the split equality problem. ©2017 All rights reserved.

Keywords: Metric projection, monotone operator, nonexpansive mapping, split feasibility problem, variational inequality.

1. Introduction

In this paper, we always assume that H_1 and H_2 are real Hilbert spaces endowed with inner products and induced norms denoted by $\langle \cdot, \cdot \rangle$ and $\| \cdot \|$, respectively, while H refers to as any of these spaces. Let D be a nonempty closed and convex subset of H . Recall that Proj_D^H is said to be a metric projection from H onto D iff

$$\|x - \text{Proj}_D^H x\| \leq \|x - y\|, \quad \forall x \in H, y \in D.$$

It is known that

$$\langle x - y, \text{Proj}_D^H x - \text{Proj}_D^H y \rangle \geq \|\text{Proj}_D^H x - \text{Proj}_D^H y\|^2, \quad \forall x, y \in H.$$

Moreover, $\text{Proj}_D^H x$ is also characterized by the fact $P_D x \in C$ and

$$\langle x - \text{Proj}_D^H x, y - \text{Proj}_D^H x \rangle \leq 0,$$

and

$$\|x - y\|^2 \geq \|x - \text{Proj}_D^H x\|^2 + \|y - \text{Proj}_D^H x\|^2, \quad \forall x \in H, y \in C.$$

Recall that a mapping $M : H \rightarrow H$ is said to be contractive iff there exists a constant $\kappa \in (0, 1)$ such that

$$\|Mx - My\| \leq \kappa \|x - y\|, \quad \forall x, y \in H.$$

Recall that $M : H \rightarrow H$ is said to be contractive iff

$$\|Mx - My\| \leq \|x - y\|, \quad \forall x, y \in H.$$

Also, recall that $M : H \rightarrow H$ is said to be averaged iff it can be written as the average of the identity mapping and a nonexpansive mapping, i.e., $M = (1 - \alpha)I + \alpha N$ where $\alpha \in (0, 1)$ and $N : H \rightarrow H$ is nonexpansive and I is the identity operator on H . Recall that $M : H \rightarrow H$ is said to be firmly nonexpansive iff

$$\|Mx - My\|^2 \leq \|x - y\|^2 - \|x - y - (Mx - My)\|^2, \quad \forall x, y \in H.$$

We note here that averaged mappings are nonexpansive. Further, firmly nonexpansive mappings are averaged. We also remark here that metric projections on nonempty closed and convex subsets are averaged. If $T = (1 - \alpha)N + \alpha A$, where $A : H \rightarrow H$ is averaged, $N : H \rightarrow H$ is nonexpansive and $\alpha \in (0, 1)$, then T is averaged. The composite of finitely many averaged mappings is still averaged. Recently, fixed point methods of nonexpansive mappings have been studied for several convex optimization problems; see [1, 8, 14, 17] and the references therein.

Recall that a mapping $F : H \rightarrow H$ is said to be monotone iff

$$\langle Fx - Fy, x - y \rangle \geq 0, \quad \forall x, y \in H.$$

Recall that $F : H \rightarrow H$ is said to be inverse-strongly monotone iff there exists a constant $\nu > 0$ such that

$$\langle Fx - Fy, x - y \rangle \geq \nu \|Fx - Fy\|^2, \quad \forall x, y \in H.$$

In such a case, we also say that F is ν -inverse-strongly monotone. Recall that $F : H \rightarrow H$ is said to be strongly monotone iff there exists a constant $\nu > 0$ such that

$$\langle Fx - Fy, x - y \rangle \geq \nu \|x - y\|^2, \quad \forall x, y \in H.$$

In such a case, we also say that F is ν -strongly monotone. Recall that $F : H \rightarrow H$ is said to be Lipschitz continuous iff there exists $L > 0$ such that

$$\|Fx - Fy\| \leq L \|x - y\|, \quad \forall x, y \in H.$$

In such case, we also say that F is L -Lipschitz continuous. If F is ν -inverse-strongly monotone, then it is $\frac{1}{\nu}$ -Lipschitz continuous and monotone. Let F be a (firmly) nonexpansive mapping and define a mapping $T : H \rightarrow H$ by $Tx = (I - F)x$, for all $x \in H$. Then T is $\frac{1}{2}$ -inverse-strongly monotone. Recently, zero point problems of monotone (accretive) operators have been extensively investigated by many authors via fixed point methods; see [2, 3, 10, 15, 16] and the references therein.

Let C and Q be nonempty closed convex subsets of H_1 and H_2 , respectively. Let $\text{Proj}_C^{H_1}$ and $\text{Proj}_Q^{H_2}$ be the metric projections onto C and Q , respectively. Recall that the split feasibility problem is to find a point $x \in H_1$ such that

$$x \in C, \quad Ax \in Q,$$

where $A : H_1 \rightarrow H_2$ is a bounded linear operator. From now on, we use $\text{Sol}(\text{SFP})$ to denote the solution set of the split feasibility problem, that is, $\text{Sol}(\text{SFP}) := \{x \in H_1, x \in C, Ax \in Q\}$. The split feasibility problem is quite general. It includes many important problems, such as, variational inequality problems, complementary problems, equilibrium problems, as special cases.

In 1994, Censor and Elfving [6] first introduced the split feasibility problem in finite dimensional spaces. Since then, the split feasibility problem has been extensively studied by many authors due to its extensive applications in signal processing and image reconstruction; see [4] and the references therein. Recently, it is also found that the split feasibility problem could also be applied to study the intensity-modulated radiation therapy; see, for example, [6, 7] and the references therein.

It is well-known that if $\text{Sol}(\text{SFP})$ is not empty, then the split feasibility problem is equivalent to a fixed point problem

$$P_C(x - \gamma A^*(I - P_Q)Ax) = x, \quad (1.1)$$

where $\gamma > 0$ is a constant and A^* is the adjoint operator of A . The split feasibility problem has recently been investigated via fixed point methods; see [9, 11, 13, 18, 20] and the references therein. Define a mapping A^γ by

$$A^\gamma x = x - \gamma A^*(I - P_Q)Ax.$$

Then (1.1) is reduced to $x = P_C A^\gamma x$. It is easy to see that $\text{Fix}(A^\gamma) = A^{-1}(Q)$ and hence $\text{Sol}(\text{SFP}) = C \cap \text{Fix}(A^\gamma) = \text{Fix}(P_C A^\gamma)$ for sufficiently small $\gamma > 0$; see Zhou and Wang [20] for the details.

The rest of the paper is organized as follows. Section 2 contains several useful lemmas. In Section 3, we introduce a CQ type iterative for the split feasibility problem. A strong convergence theorem is established in the framework of Hilbert spaces. We also provide an application to the split equality problem.

2. Preliminaries

Lemma 2.1 ([19]). *Let H be a Hilbert space. Then there exists a strictly increasing continuous convex function $W : [0, \infty) \rightarrow [0, \infty)$ with $W(0) = 0$ such that*

$$a\|x\|^2 + (1-a)\|y\|^2 \geq \|ax + (1-a)y\|^2 + (1-a)aW(\|x-y\|), \quad \forall a \in [0, 1]$$

for all $x, y \in B_r(0) := \{x \in H : \|x\| \leq r\}$, where r is some positive real number. In particular, we have

$$a\|x\|^2 + (1-a)\|y\|^2 \geq \|ax + (1-a)y\|^2, \quad \forall a \in [0, 1].$$

Lemma 2.2 ([12]). *Let $\{a_n\}$ be a sequence of nonnegative real numbers such that $a_{n+1} \leq (1-t_n)a_n + b_n + c_n$, for all $n \geq 0$, where $\{c_n\}$ is a sequence of nonnegative real numbers, $\{t_n\} \subset (0, 1)$, and $\{b_n\}$ is a sequence of real numbers. Assume that*

- (a) $\limsup_{n \rightarrow \infty} \frac{b_n}{t_n} \leq 0$, $\sum_{n=0}^{\infty} t_n = \infty$;
- (b) $\sum_{n=0}^{\infty} c_n < \infty$.

Then $\lim_{n \rightarrow \infty} a_n = 0$.

The following two lemmas are not hard to derive.

Lemma 2.3. *Let $\text{Proj}_C^H : H \rightarrow C$ be the metric projection from H on a nonempty, closed, and convex subset of C . Then the following conclusions hold true*

- (a) $\langle P_C^H x - P_C^H y, x - y \rangle \geq \|P_C^H x - P_C^H y\|^2$, $x, y \in H$.
- (b) Given $x \in H$ and $z \in C$, then $z = P_C^H x$ iff there holds the inequality $\langle x - z, y - z \rangle \leq 0$, $y \in C$.
- (c) $\|P_C^H x - P_C^H y\|^2 \leq \|x - y\|^2 - \|(I - P_C^H)x - (I - P_C^H)y\|^2$, $\forall x, y \in H$.
- (d) $\langle (I - P_C^H)x - (I - P_C^H)y, x - y \rangle \geq \|(I - P_C^H)x - (I - P_C^H)y\|^2$, $\forall x, y \in H$.

Lemma 2.4. *Let H be a Hilbert space. Then the following inequality holds.*

$$\|x + y\|^2 = \|x\|^2 + \|y\|^2 + 2\langle x, y \rangle \leq \|x\|^2 + 2\langle y, x + y \rangle.$$

3. Main results

Theorem 3.1. *Let C and Q be two nonempty, closed, and convex subsets of real Hilbert spaces H_1 and H_2 , respectively. Let $\text{Proj}_C^{H_1}$ and $\text{Proj}_Q^{H_2}$ be the metric projections onto C and Q , respectively. Let $A : H_1 \rightarrow H_2$ be a bounded linear operator and let $f : H_1 \rightarrow H_1$ be a κ -contractive mapping. Assume that $\text{Sol}(\text{SFP}) \neq \emptyset$. Let $\{x_n\}$ be a sequence generated in the following iterative algorithm*

$$x_1 \in H, \quad x_{n+1} = \text{Proj}_C^{H_1}(\alpha_n f(x_n) + (1 - \alpha_n)(x_n - \beta_n A^*(I - \text{Proj}_Q^{H_2})Ax_n)), \quad (3.1)$$

where $\{\alpha_n\}$ is a sequence in $(0, 1)$ such that $\lim_{n \rightarrow \infty} \alpha_n = 0$, $\sum_{n=1}^{\infty} \alpha_n = \infty$ and $\sum_{n=1}^{\infty} |\alpha_n - \alpha_{n+1}| < \infty$ and

$\{\beta_n\}$ is a sequence such that $\sum_{n=1}^{\infty} |\beta_n - \beta_{n+1}| < \infty$, $0 < p \leq \beta_n \leq q < \frac{2}{\|A\|^2}$, where p and q are two real numbers. Then $\{x_n\}$ converges strongly to a point x^* in $\text{Sol}(\text{SFP})$ and $x^* = P_{\text{Sol}(\text{SFP})} f(x^*)$.

Proof. Since $\text{Sol}(\text{SFP})$ is nonempty, closed, and convex, we see that projection $P_{\text{Sol}(\text{SFP})} x$, $\forall x \in H_1$ onto $\text{Sol}(\text{SFP})$ is well-defined. Since $\text{Proj}_{\text{Sol}(\text{SFP})}^{H_1} f$ is κ -contractive, we see that $P_{\text{Sol}(\text{SFP})} f$ has a unique fixed point. Next, we use x^* to denote the unique fixed point, that is, $x^* = \text{Proj}_{\text{Sol}(\text{SFP})}^{H_1} f(x^*)$.

Define a mapping $F : H_1 \rightarrow H_1$ by $Fx = A^*(I - \text{Proj}_Q^{H_2})Ax$. Then (3.1) becomes

$$x_1 \in H, \quad x_{n+1} = \text{Proj}_C^{H_1} (\alpha_n f(x_n) + (1 - \alpha_n)(x_n - \beta_n AFx_n)).$$

Using Lemma 2.3, we have

$$\begin{aligned} \langle Fx - Fy, x - y \rangle &= \langle (I - \text{Proj}_Q^{H_2})Ax - (I - \text{Proj}_Q^{H_2})Ay, Ax - Ay \rangle \\ &\geq \|(I - \text{Proj}_Q^{H_2})Ax - (I - \text{Proj}_Q^{H_2})Ay\|^2 \\ &\geq \frac{1}{\|A\|^2} \|A^*(I - \text{Proj}_Q^{H_2})Ax - A^*(I - \text{Proj}_Q^{H_2})Ay\|^2 \\ &= \frac{1}{\|A\|^2} \|Fx - Fy\|^2. \end{aligned} \quad (3.2)$$

This shows that F is $\frac{1}{\|A\|^2}$ -inverse-strongly monotone. Next, we prove $F^{-1}(0) = A^{-1}(Q)$. For all $x \in A^{-1}(Q)$, we find from the definition of F that $A^{-1}(Q) \subset F^{-1}(0)$. Next, we prove $F^{-1}(0) \subset A^{-1}(Q)$. It is easy to see that $A^{-1}(Q) \subset F^{-1}(0)$. Letting $x \in F^{-1}(0)$, we have $Fx = 0$. Since the split feasibility problem is consistent, we can take a point $y \in \text{Sol}(\text{SFP})$. This implies $Ay = \text{Proj}_Q^{H_2} Ay$. Hence, $Fy = 0$. Using (3.2), we have

$$\|(I - \text{Proj}_Q^{H_2})Ax\|^2 \leq \langle Fx - Fy, x - y \rangle = 0,$$

which implies that $x \in A^{-1}(Q)$, that is, $F^{-1}(0) \subset A^{-1}(Q)$. This shows that $F^{-1}(0) = A^{-1}(Q)$. Putting $y_n = x_n - \beta_n Fx_n$, we have

$$\begin{aligned} \|y_n - x^*\|^2 &= \|\beta_n(Fx_n - Fx^*) - (x_n - x^*)\|^2 \\ &= \beta_n^2 \|Fx_n - Fx^*\|^2 - 2\beta_n \langle Fx_n - Fx^*, x_n - x^* \rangle + \|x_n - x^*\|^2 \\ &\leq \beta_n^2 \|Fx_n\|^2 - \frac{2\beta_n}{\|A\|^2} \|Fx_n\|^2 + \|x_n - x^*\|^2 \\ &= \|x_n - x^*\|^2 - \left(\frac{2\beta_n}{\|A\|^2} - \beta_n^2\right) \|Fx_n\|^2. \end{aligned} \quad (3.3)$$

Since $0 < p \leq \beta_n \leq q < \frac{2}{\|A\|^2}$, we have $\|y_n - x^*\| \leq \|x_n - x^*\|$. This implies that

$$\begin{aligned} \|x_{n+1} - x^*\| &= \|P_C(\alpha_n f(x_n) + (1 - \alpha_n)y_n) - P_C x^*\| \\ &\leq \|\alpha_n(f(x_n) - x^*) + (1 - \alpha_n)(y_n - x^*)\| \\ &\leq \alpha_n \|f(x_n) - f(x^*)\| + \alpha_n \|f(x^*) - x^*\| + (1 - \alpha_n) \|y_n - x^*\| \\ &\leq \alpha_n \|f(x^*) - x^*\| + (1 - \alpha_n(1 - \kappa)) \|x_n - x^*\| \\ &\leq \max\left\{\frac{\|f(x^*) - x^*\|}{1 - \kappa}, \|x_n - x^*\|\right\}. \end{aligned}$$

By mathematical induction, we find that

$$\|x_{n+1} - x^*\| \leq \max\left\{\frac{\|f(x^*) - x^*\|}{1 - \kappa}, \|x_1 - x^*\|\right\}.$$

This shows that $\{x_n\}$ is bounded. Since F is $\frac{1}{\|A\|^2}$ -inverse-strongly monotone, we have

$$\begin{aligned}\|(I - \beta_n F)x - (I - \beta_n F)y\|^2 &= \|\beta_n(Fx - Fy) - (x - y)\|^2 \\ &= \|x - y\|^2 - 2\beta_n \langle Fx - Fy, x - y \rangle + \beta_n^2 \|Fx - Fy\|^2 \\ &\leq \|x - y\|^2 - \frac{2\beta_n}{\|A\|^2} \|Fx - Fy\|^2 + \beta_n^2 \|Fx - Fy\|^2 \\ &= \|x - y\|^2 - \left(\frac{2\beta_n}{\|A\|^2} - \beta_n^2\right) \|Fx - Fy\|^2.\end{aligned}$$

Since $0 < p \leq \beta_n \leq q < \frac{2}{\|A\|^2}$, we find that $(I - \beta_n F)$ is nonexpansive. It follows that

$$\begin{aligned}\|x_{n+1} - x_n\| &\leq \|(\alpha_n f(x_n) + (1 - \alpha_n)y_n) - (\alpha_{n-1}f(x_{n-1}) + (1 - \alpha_{n-1})y_{n-1})\| \\ &\leq \alpha_n \|f(x_n) - f(x_{n-1})\| + (1 - \alpha_n) \|y_n - y_{n-1}\| + |\alpha_n - \alpha_{n-1}| \|f(x_{n-1}) - y_{n-1}\| \\ &\leq \alpha_n \kappa \|x_n - x_{n-1}\| + (1 - \alpha_n) \|(I - \beta_n F)x_n - (I - \beta_n F)x_{n-1}\| \\ &\quad + (1 - \alpha_n) \|(I - \beta_n F)x_{n-1} - (I - \beta_{n-1}F)x_{n-1}\| + |\alpha_n - \alpha_{n-1}| \|f(x_{n-1}) - y_{n-1}\| \\ &\leq (1 - (1 - \kappa)\alpha_n) \|x_n - x_{n-1}\| + |\beta_n - \beta_{n-1}| \|Fx_{n-1}\| + |\alpha_n - \alpha_{n-1}| \|f(x_{n-1}) - y_{n-1}\|.\end{aligned}$$

Using Lemma 2.2, we find that

$$\lim_{n \rightarrow \infty} \|x_{n+1} - x_n\| = 0. \quad (3.4)$$

Since $\|\cdot\|^2$ is convex, we find from (3.3) that

$$\begin{aligned}\|x_{n+1} - x^*\|^2 &\leq \|(\alpha_n f(x_n) + (1 - \alpha_n)y_n) - x^*\|^2 \\ &\leq \alpha_n \|f(x_n) - x^*\|^2 + (1 - \alpha_n) \|y_n - x^*\|^2 \\ &\leq \alpha_n \|f(x_n) - x^*\|^2 + (1 - \alpha_n) \|x_n - x^*\|^2 - (1 - \alpha_n) \left(\frac{2\beta_n}{\|A\|^2} - \beta_n^2\right) \|Fx_n\|^2.\end{aligned}$$

It follows that

$$\begin{aligned}(1 - \alpha_n) \beta_n \left(\frac{2}{\|A\|^2} - \beta_n\right) \|Fx_n\|^2 &\leq \alpha_n \|f(x_n) - x^*\|^2 + (1 - \alpha_n) \|x_n - p\|^2 - \|x_{n+1} - p\|^2 \\ &\leq \alpha_n \|f(x_n) - x^*\|^2 + \|x_n - p\|^2 - \|x_{n+1} - p\|^2 \\ &\leq \alpha_n \|f(x_n) - x^*\|^2 + (\|x_n - p\| + \|x_{n+1} - p\|) \|x_{n+1} - x_n\|.\end{aligned}$$

Using the restrictions imposed on $\{\alpha_n\}$ and $\{\beta_n\}$, we find from (3.4) that $\lim_{n \rightarrow \infty} \|Fx_n\| = 0$. This implies $\lim_{n \rightarrow \infty} \|x_n - y_n\| = 0$. Since F is Lipschitz continuous, we find that $\lim_{n \rightarrow \infty} \|Fy_n\| = 0$.

We are now in a position to show that

$$\limsup_{n \rightarrow \infty} \langle f(x^*) - x^*, y_n - x^* \rangle \leq 0.$$

Take a subsequence $\{y_{n_j}\}$ of $\{y_n\}$ such that

$$\limsup_{n \rightarrow \infty} \langle f(x^*) - x^*, y_n - x^* \rangle = \lim_{j \rightarrow \infty} \langle f(x^*) - x^*, y_{n_j} - x^* \rangle.$$

Without loss of generality, we may assume that $\{y_{n_j}\}$ converges weakly to \hat{x} . We find that $\hat{x} \in F^{-1}(0)$. Indeed, Since F is $\frac{1}{\|A\|^2}$ -inverse-strongly monotone, we have

$$\|A\|^2 \langle Fy_{n_j} - F\hat{x}, x_{n_j} - \hat{x} \rangle \geq \|Fy_{n_j} - F\hat{x}\|^2. \quad (3.5)$$

Letting $j \rightarrow \infty$ in (3.5), we arrive at

$$0 \geq \|F\hat{x}\|^2,$$

which means that $F\hat{x} = 0$. This further implies that

$$\limsup_{n \rightarrow \infty} \langle f(x^*) - x^*, y_n - x^* \rangle = \lim_{j \rightarrow \infty} \langle f(x^*) - x^*, y_{n_j} - x^* \rangle \leq 0.$$

Finally, we prove $x_n \rightarrow x^*$. Using Lemma 2.4, we find that

$$\begin{aligned}
 \|x_{n+1} - x^*\|^2 &\leq \|(1 - \alpha_n)(y_n - x^*) + \alpha_n(f(x_n) - x^*)\|^2 \\
 &= (1 - \alpha_n)^2 \|y_n - x^*\|^2 + \alpha_n^2 \|f(x_n) - x^*\|^2 + 2\alpha_n(1 - \alpha_n) \langle y_n - x^*, f(x_n) - x^* \rangle \\
 &\leq (1 - 2\alpha_n + \alpha_n^2) \|y_n - x^*\|^2 + \alpha_n^2 \|f(x_n) - x^*\|^2 + 2\alpha_n(1 - \alpha_n) \|y_n - x^*\| \|f(x_n) - f(x^*)\| \\
 &\quad + 2\alpha_n(1 - \alpha_n) \langle y_n - x^*, f(x^*) - x^* \rangle \\
 &\leq (1 - 2\alpha_n + \alpha_n^2 + 2\alpha_n(1 - \alpha_n)\kappa) \|x_n - x^*\|^2 + \alpha_n^2 \|f(x_n) - x^*\|^2 \\
 &\quad + 2\alpha_n(1 - \alpha_n) \langle y_n - x^*, f(x^*) - x^* \rangle \\
 &= (1 - \alpha_n(2 - \alpha - 2(1 - \alpha_n)\kappa)) \|x_n - x^*\|^2 + \alpha_n \left(\alpha_n \|f(x_n) - x^*\|^2 \right. \\
 &\quad \left. + 2(1 - \alpha_n) \langle y_n - x^*, f(x^*) - x^* \rangle \right) \\
 &= (1 - \alpha_n(2 - \alpha - 2(1 - \alpha_n)\kappa)) \|x_n - x^*\|^2 \\
 &\quad + \alpha_n(2 - \alpha - 2(1 - \alpha_n)\kappa) \frac{\alpha_n \|f(x_n) - x^*\|^2 + 2(1 - \alpha_n) \langle y_n - x^*, f(x^*) - x^* \rangle}{2 - \alpha - 2(1 - \alpha_n)\kappa}.
 \end{aligned}$$

Using Lemma 2.2, we find that $x_n \rightarrow x^*$ as $n \rightarrow \infty$. This completes the proof. \square

Let H_1 , H_2 , and H_3 be real Hilbert spaces, let $C \subset H_1$ and $Q \subset H_2$ be two nonempty, closed, and convex sets, and let $A : H_1 \rightarrow H_3$ and $B : H_2 \rightarrow H_3$ be two bounded linear operators. Recall that the split equality problem is to

$$\text{find } x \in C \text{ and } y \in Q \text{ such that } Ax = By.$$

We use Ω to denote the solution set of the split equality problem, which was first introduced and studied by Moudafi and Al-Shemas [13]. By virtue of the product space techniques, we can convert the split equality problem to another specific split feasibility problem. To see this, set $S = C \times Q$ and define

$$G = [A, -B], \quad \omega = [x, y]^T.$$

With these notations, we know that solving the split equality problem is equivalent to finding a point $\omega \in S$ such that $G\omega = 0$. Assuming that the split equality problem is consistent, i.e., $\Omega \neq \emptyset$, then it is not hard to see that $\omega \in S$ solves the split equality problem if and only if it solves the operator equation $G^*G\omega = 0$, where G^* is the adjoint operator of G . It is clear that $G^*G : H_1 \times H_2 \rightarrow H_1 \times H_2$ is $\frac{1}{\|G\|^2}$ -inverse strongly monotone. By using Theorem 3.1, we deduce immediately the following result.

Corollary 3.2. *Let H_1 , H_2 , and H_3 be real Hilbert space. Let $C \subset H_1$ and $Q \subset H_2$ be two nonempty, closed, and convex sets of real Hilbert spaces H_1 and H_2 , respectively. Let $A : H_1 \rightarrow H_3$ and $B : H_2 \rightarrow H_3$ be two bounded linear operators. Let $f : H_1 \rightarrow H_1$ be a κ -contractive mapping. Suppose that the $\Omega \neq \emptyset$ is consistent. Let $\{\alpha_n\}$ and $\{\beta_n\}$ be given as in Theorem 3.1. Let a sequence $\{\omega_n\}$ be generated by the algorithm*

$$\omega_1 \in H_1 \times H_2, \quad \omega_{n+1} = \text{Proj}_S[\alpha_n f(\omega_n) + (1 - \alpha_n)(\omega_n - \beta_n G^*G\omega_n)], \quad n \geq 1.$$

Then $\{\omega_n\}$ converges in norm to $\omega^ = P_\Omega f(\omega^*)$, that is, ω^* is a unique solution of the variational inequality*

$$\langle f(\omega^*) - \omega^*, \omega^* - y \rangle \geq 0, \quad \forall y \in \Omega.$$
