Electro-oxidation of tetramethyltetrathiafulvalene (TMTTF) in the presence of the chiral anion (1S)-camphor-10-sulfonate (S-camphSO_3^-) in tetrahydrofuran/water medium afforded a 1/1 salt formulated as $\text{TMTTF}\cdot\text{S-camphSO}_3\cdot 2\text{H}_2\text{O}$ or $2\text{-}(4,5\text{-dimethyl-1,3-dithiol-2-ylidene})\text{-}4,5\text{-dimethyl-1,3-dithiole radical ion (1+)}\text{ [}(1\text{S})\text{-}7,7\text{-dimethyl-2-oxobicyclo[2.2.1]heptan-1-yl]methanesulfonate dihydrate, } \text{C}_{10}\text{H}_{12}\text{S}_4^+\text{C}_{10}\text{H}_{15}\text{O}_4\text{S}^-\text{.2H}_2\text{O}$. In this salt, two independent TMTTF units are present but, in both cases, the observed bond lengths and especially the central $\text{C}=\text{C}$ distance [1.392 (6) and 1.378 (6) Å] are in agreement with a complete oxidation of TMTTF which is thus present as TMTTF^+ radical cations. These cations form one-dimensional stacks in which they are associated two by two, forming dimers with short [3.472 (1) to 3.554 (2) Å] $\text{S}\cdots\text{S}$ contacts. The two S-camphSO_3^- anions present also form stacks and are connected with each other *via* the water molecules with many $\text{O}-\text{H}\cdots\text{O}$ hydrogen bonds ranging from 1.86 (3) to 2.15 (4) Å; the $\text{O}-\text{H}\cdots\text{O}$ hydrogen-bonding network can be described as being constituted of $\text{C}_2^2(6)$ chains bearing $\text{R}_3^3(11)$ lateral rings. On the other hand, the columns of cations and anions are connected through $\text{C}-\text{H}\cdots\text{O}$ hydrogen bonds, forming a system expanding in three directions; finally, the result is a three-dimensional network of $\text{O}-\text{H}\cdots\text{O}$ and $\text{C}-\text{H}\cdots\text{O}$ hydrogen bonds.

1. Chemical context

Chiral molecular conductors may display interesting properties such as the magneto-chiral anisotropy effect; the different strategies of access to these materials have been recently reviewed (Avarvari & Wallis, 2009; Pop *et al.*, 2014). Among these possible strategies, a straightforward *a priori* approach consists of combining, through electrocrystallization experiments, chiral counter-anions, existing in enantiopure form, to TTF-based radical-cations; in this context, due to the commercial availability of the parent acid $\text{S-camphSO}_3\text{H}$, the anion S-camphSO_3^- appears to be a ready choice and, in fact, it has already been used to obtain the salt $(\text{EDT-TTFI}_2)_2\text{S-camphSO}_3\text{H}_2\text{O}$, where EDT-TTFI₂ is diiodoethylenedithiotetrathiafulvalene (Brezgunova *et al.*, 2010). In addition, it is worth mentioning a more general review relating to conducting radical cation salts with organic anions, especially anions derived from carboxylic and sulfonic organic acids (Geiser & Schlueter, 2004).

OPEN ACCESS

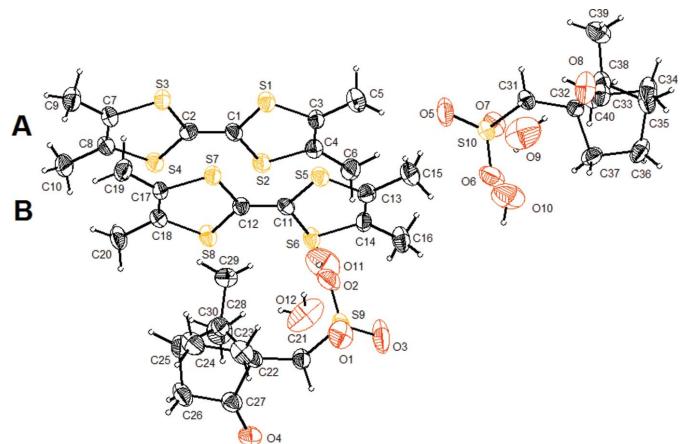

Figure 1

The asymmetric unit of the title compound, showing the atom-numbering scheme. Displacement ellipsoids are drawn at the 50% probability level. H atoms are represented as small spheres of arbitrary radii.

2. Structural commentary

The title compound crystallizes with two independent TMTTF cations, two independent S-camphSO₃⁻ anions and four water molecules (Fig. 1) in the asymmetric unit. The geometries of the two types (*A* and *B*) of TMTTF units (Fig. 1), are rather similar despite the fact that *A* and *B* are crystallographically independent; in both case, the observed bond lengths (see *e.g.* Penicaud *et al.*, 1990; Shibaeva, 1984) and especially the central C=C distance [1.392 (6) Å in *A* and 1.378 (6) Å in *B*] are in agreement with a complete oxidation of TMTTF which is thus present as TMTTF⁺ radical-cations, in agreement also with the 1/1 cation/anion balance of this salt.

3. Packing of the donors

The cations form columns along the a axis in which the two types, A and B , of TMTTF units alternate (Fig. 2). The overall

Symmetry codes: (i) $x+1, y, z$; (ii) $x, y+1, z$; (iii) $-x+1, y+\frac{1}{2}, -z+1$; (iv) $-x+1, y-\frac{1}{2}, -z+2$; (v) $x-1, y, z$.

arrangement of the donors can be described as monodimensional since these stacks are isolated. Starting from one particular column, a set of equivalent columns may be deduced by translation along b , thus generating a cationic layer lying in the ab plane; however, there is no vicinity relation between two successive donors belonging to two different stacks of the same layer, except for proximity of the external methyl groups. When looking in the c -axis direction, successive layers are completely separated by slabs of anions; moreover, the orientation of the donors is different in two consecutive cationic layers since they adopt a herringbone arrangement.

The packing of the donors within one stack is shown more precisely in Fig. 3. The two alternating molecules (*A* and *B*) are nearly parallel, the dihedral angle between their mean

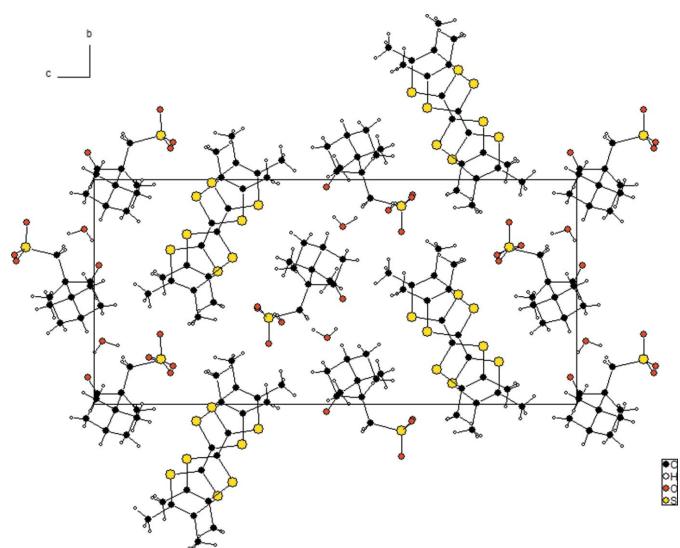

Figure 2
Overall view, along the a axis, of the crystal packing.

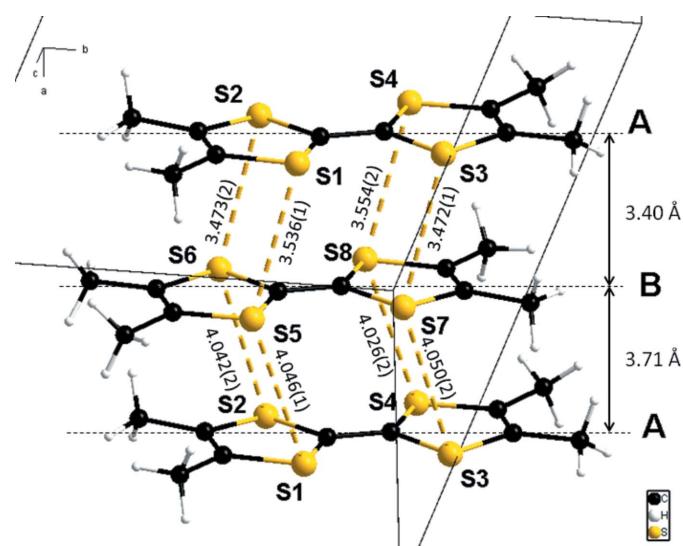

Figure 3
Packing of the donors: S · · · S contact distances within a stack, in the case of the two different inter-donor intervals.

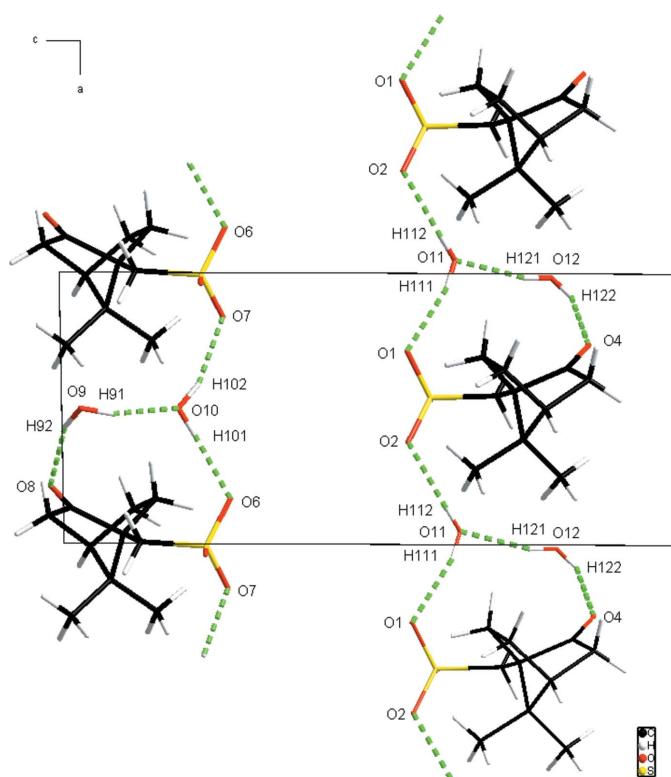

Figure 4

planes being only 0.24°. Within a stack, two independent intermolecular intervals alternate with mean inter-plane distances of 3.40 and 3.71 Å. One can conclude in favour of the presence of dimers since the four intermolecular S···S contacts corresponding to the smaller interval range from 3.472 (1) to 3.554 (2) Å (Fig. 3) and thus are shorter than twice the van der Waals radius of sulfur (3.6–3.7 Å; Bondi, 1964; Pauling, 1960); within a dimer the *A* and *B* units adopt a bond-over-ring (Williams *et al.*, 1992) relative arrangement. On the other hand, all S···S distances across the larger interval exceed the van der Waals distance, ranging from 4.026 (2) to 4.050 (2) Å.

4. Supramolecular features

The S-camphSO₃ anions stack along the *a* axis and are connected with each other *via* the water molecules with many O—H···O hydrogen bonds ranging from 1.86 (3) Å to 2.15 (4) Å (Table 1). The oxygen from one sulfonate is linked to the oxygen of the neighbouring sulfonate through a bridging water molecule, while the oxygen of this latter is linked to the H atom of another water molecule, which is also connected to the oxygen of the ketone group, through O—H···O interactions (Fig. 4). Thus, in Etter's classification (Etter, 1990), the O—H···O hydrogen-bonding network can be described as being constituted of *C*₂²(6) chains bearing *R*₃²(11) lateral rings. On the other hand, the columns of cations

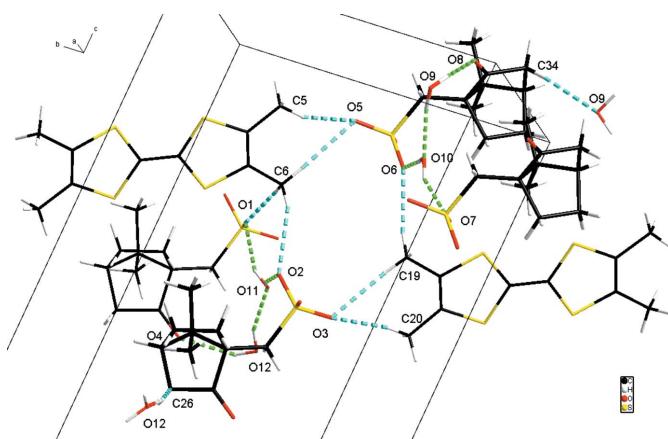

Figure 5
Partial view of the crystal packing, showing both O—H···O bonds (green dashed lines) and the C—H···O contacts (blue dashed lines).

and anions are connected through C—H···O hydrogen bonds, forming a system expanding in all three directions (Fig. 5 and Table 1); finally, the result is a three-dimensional network of O—H···O and C—H···O hydrogen bonds.

5. Synthesis and crystallization

Synthesis of the supporting electrolyte (1*S*)-camphor-10-sulfonic acid (Aldrich) (2.32 g, 10 mmol) was dissolved in water (50 ml), then 10 ml of a 1.0 mol l⁻¹ methanolic solution of tetrabutyl ammonium hydroxide (Aldrich) were added dropwise. This aqueous solution was stirred for one hour then extracted twice with dichloromethane (2 × 100 ml). After drying over MgSO₄, evaporation of dichloromethane afforded tetrabutylammonium *S*-camphorsulfonate ($\text{Bu}_4\text{N}^+\text{·S-camph-SO}_3^-$) (4.50 g, yield 95%), m.p. 410–412 K. Elemental analysis: calculated for C₂₆H₅₁NO₄S: C 65.92, H 10.85, N 2.96, S 6.77%; found: C 65.77, H 11.25, N 2.91, S 6.76%. ¹H NMR (300 MHz, CDCl₃): δ 0.82 (3H, s), 1.00 (12H, t, *J* = 7.3 Hz), 1.15 (3H, s), 1.32 (1H, m), 1.45 (8H, pseudo sextuplet), 1.66 (8H, m), 1.83 (3H, pseudo *t*), 1.99 (2H, m), 2.29 (1H, m), 2.83 (2H, m), 3.31 (8H, pseudo *q*).

Electrocrystallization of TMTTF·S-camphSO₃·2H₂O A conventional H-shaped cell was charged with 142 mg (0.3 mmol) of $\text{Bu}_4\text{N}^+\text{·S-camphSO}_3^-$ dissolved in 20 ml of a 98/2 (v/v) tetrahydrofuran–water mixture, degassed with argon. TMTTF (7.8 mg, 0.03 mmol) was introduced in the anodic arm and was then electro-oxidized under galvanostatic conditions with stepwise increases of the applied current (Anzai *et al.*, 1995): 0.5 μA for 3 days, then 1 μA for 4 days, 2 μA for 3 days and finally 5 μA for 8 days; afterwards, the black needles of TMTTF·S-camphSO₃·2H₂O, deposited at the platinum wire anode, were collected. The electrocrystallization was conducted at room temperature except during the 6 last days during which the cell was cooled to 283 K.

Unsuccessful electrocrystallization experiments Electrocrystallizations, using $\text{Bu}_4\text{N}^+\text{·S-camphSO}_3^-$ (or other camphSO₃[−] salts) as supporting electrolyte, were attempted,

in various solvent conditions, with the following donors: TTF itself, BEDT-TTF, ethylenedithiotetrathiafulvalene (EDT-TTF) and tetramethyltetraselenafulvalene (TMTSF), without affording usable crystals. Thus, TMTTF·S-camphSO₃·2H₂O and (EDT-TTFI₂)₂·S-camphSO₃·H₂O (Brezgunova *et al.*, 2010), are presently the only known salts associating the camphorsulfonate anion to TTF donors.

6. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 2. All H atoms attached to C were fixed geometrically and treated as riding with C—H = 0.96 Å (idealized methyl group, torsion angle from electron density), 0.97 Å (methylene) or 0.98 Å (methine), with $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$ or $U_{\text{iso}}(\text{H}) = 1.5U_{\text{eq}}(\text{methyl})$. The H atoms of the water molecule were located in a difference electron density map and then refined as riding on their parent O atoms with $U_{\text{iso}}(\text{H}) = 1.5U_{\text{eq}}(\text{O})$.

Acknowledgements

The authors acknowledge Mrs Valerie Bonnin for the elemental analysis.

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger. The H atoms on the water molecules were added by Fourier difference map and then restrained with 13 *DFIX* commands between O and H and H and H on the 4 water molecules.
