## **ABSTRACT**

This report documents the measured post irradiation dimensional change in the AGC-1 samples. The AGC-1 capsule is the first in six planned irradiation capsules comprising the Advanced Graphite Creep (AGC) test series. AGC-1 irradiation began September 5, 2009 in the Advanced Test Reactor (ATR) and was completed on January 8, 2011. The capsule was cooled for 3 months in the ATR Canal, and then shipped to MFC in April 2011 for disassembly and sample extraction. After extraction the samples were shipped to the INL Research Center (IRC) for initial post-irradiation examination (PIE) and storage in the irradiated graphite vault. The AGC-1 capsule design contained “matched pair” samples to ascertain the irradiation-induced dimensional changes and levels of creep experienced in different graphite types. The irradiation-induced dimensional changes and creep levels are determined by comparing the total dimensional change for stressed and unstressed samples of the same type of graphite exposed to the same dose levels and at similar temperatures. Under irradiation creep (i.e. permanent strain due to irradiation, stress, and temperature) the stressed samples should demonstrate more dimensional change than the unstressed samples. This additional dimensional change in the stressed samples is designated as “irradiation-induced creep” in graphite. The data are further presented using the parameters influencing dimensional change in graphite; levels of induced stress, temperature, graphite type, and dose. However, the AGC-1 post-irradiation examination is a significant endeavor and this data report serves to provide irradiation-induced dimensional change data for AGC capsule design refinement as well as a status on the progress of the PIE activities. The dimensional changes of both the samples and graphite body are very important to the design of the future AGC capsules (AGC-3 through AGC-6) and are provided as soon as the data are available in order to determine whether design changes to the next capsule are required. A complete evaluation of the irradiation-induced dimensional change data will be performed for a final AGC-1 PIE report that will include full analysis of pre- and post-irradiation data, with verified AGC-1 irradiation conditions of temperature and dose.

# Data Report on Post-Irradiation Dimensional Change in AGC-1 Samples

## 1. INTRODUCTION

The Next Generation Nuclear Plant (NGNP) Graphite Research & Development (R&D) program is intended to provide quantitative material property data of nuclear grade graphite to predict the material's behavior within a nuclear reactor core. The five main areas of R&D initiated to achieve these goals are (1) establishing a viable nuclear graphite supply source by collaborating with graphite manufacturers and sharing data from material test programs, (2) building a statistically defensible as-formed (virgin) material property database that provides baseline values for all pertinent material properties, (3) conducting an extensive irradiation program that focuses on irradiation creep within nuclear graphite as the critical life limiting mechanism during irradiation, (4) developing an understanding of the underlying mechanisms controlling the graphite behavior under irradiation, and (5) developing analytical models based on the quantitative data and results from the fundamental studies. All five areas are critical to knowing the material performance during reactor operation, but the materials irradiation program is key in developing the tools needed to predict the thermal, mechanical, and physical behavior of graphite under irradiation.

The NGNP graphite materials irradiation program is being performed under the Advanced Graphite Creep (AGC) test series, as described in the Graphite Technology Development Plan (TDP).<sup>1</sup> This test series exposes a variety of nuclear grade graphite types to high temperatures and a range of doses that are expected within a high temperature gas-cooled reactor (HTGR) design. In addition, based upon previous experience with these graphite core reactor designs, the phenomenon of irradiation-induced creep within the graphite is critical to the total useful lifetime of the graphite components. Irradiation-induced creep occurs under the simultaneous application of high temperatures, neutron irradiation and applied stresses within the graphite components as shown in Figure 1. Significant internal stresses within the graphite components can arise from a second phenomenon, irradiation-induced dimensional change, where the graphite physically changes: first by shrinking and then by expanding, if greater levels of irradiation dose are experienced. This disparity in material volume change can induce significant internal stresses within the graphite components. Irradiation-induced creep assists in the removal of these large internal stresses, thus reducing the risk of crack formation and component failure. Obviously, higher irradiation creep levels tend to relieve more internal stress, allowing for the components longer useful lifetimes within the core. As a consequence, the AGC test series has a significant scope dedicated to determining the irradiation-induced creep rates of the different types of nuclear graphite.

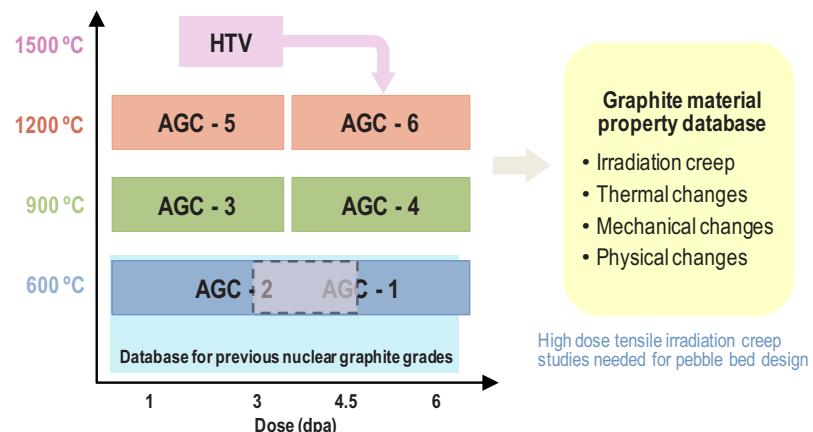

Figure 1. Irradiation dose and temperature parameters of the AGC Test series; the gray area between AGC-1 and AGC-2 is the expected dose overlap between capsule irradiation.

The traditional method for measuring irradiation-induced creep is to apply a significant load to half the samples during irradiation while leaving the remaining half of the samples unloaded. The samples under no applied load will experience only irradiation-induced dimensional change but the loaded samples will experience irradiation creep in addition to the dimensional changes. If each of the two different samples are irradiated to the same dose level and similar temperature, the measured difference in dimensional geometry between loaded and unloaded samples is the amount of irradiation-induced creep for the specific graphite type. The AGC test series uses this method to determine the irradiation-induced dimensional changes as well as irradiation creep levels for the five major types of nuclear grade graphite being considered for the NGNP. The AGC test series uses matched pair samples for each major graphite type to ascertain the irradiation-induced creep over a range of neutron dose levels, at three different applied load levels, and for three different temperatures.<sup>1</sup> The design concept of the individual AGC irradiation capsules is further explained in the sections that follow.

Before irradiation, each individual sample undergoes a series of thermal and physical (non-destructive) pre-irradiation tests.<sup>2</sup> Extensive dimensional measurements are performed in both the axial and lateral dimensions according to ASTM C559 (05).<sup>3,4,5</sup> After irradiation, the samples are recovered and the physical dimensions are re-measured using the same techniques and standards as the pre-irradiation examination.<sup>6,7</sup> Both the loaded and unloaded samples are measured with the assumption that the temperatures and doses for the matched pair samples are similar.

This data report summarizes the dimensional changes for loaded and unloaded AGC-1 samples to provide irradiation-induced dimensional change data for refinement of AGC capsule designs and to status the progress of the AGC-1 post-irradiation examination (PIE) activities. The measured dimensional changes of both graphite samples and the graphite body holding the samples are very important to the design of the future AGC capsules (AGC-3 through AGC-6). Since the design of AGC-3 and AGC-4 capsules is currently underway, the dimensional measurement data are provided as soon as available in order to determine whether design changes are required. All dimensional changes for all samples are presented as a function of dose. The data are further presented by major graphite type and applied load levels<sup>8</sup> to illustrate the influence of graphite forming processes and stress levels within the graphite components on the measured behavior. Finally, the dimensional changes to the unloaded (unstressed) minor graphite types and fuel compact matrix material are presented over the AGC-1 dose range.

## 2. DESCRIPTION OF AGC TEST SERIES

The AGC test series, consisting of six irradiation capsules, will generate irradiated graphite performance data for NGNP reactor operating conditions. The AGC test series is designed to determine the changes to specific material properties such as thermal diffusivity, thermal expansion, elastic modulus, mechanical strength, irradiation-induced dimensional change rate, and irradiation creep for a wide variety of nuclear grade graphite types over a range of high temperature and moderate doses. A series of six capsules containing graphite test specimens will be used to expose different nuclear graphite types to a dose range of 1 to 7 displacements per atom (dpa) at three different temperatures: 600, 900, and 1200°C. Since irradiation-induced creep within graphite components is considered critical to determining the operational life of the graphite core, approximately half of the irradiation creep samples will also be exposed to an applied load during exposure. This will allow a determination of the induced creep level for each graphite type at three different temperature levels and a moderate range of neutron dose.

### 2.1 General Design of AGC Capsules

The AGC test series consists of 6 irradiation capsules irradiating approximately 500 graphite samples in each capsule. As shown in Figure 1, the AGC test series is designed to irradiate graphite samples over a neutron dose range of 0.5 to 7 dpa. Two capsules must be used; one exposed to the range of 0.5–3.5 dpa and one irradiated twice as long, producing a dose range of 3–7 dpa. The first two capsules are intended to be irradiated at 600°C, the next two capsules at 900°C, and the final two at 1200°C. As explained previously, to determine the irradiation creep rate in specific types of nuclear graphite, half of the samples are placed under a mechanical load during irradiation, which is intended to accelerate dimension changes that occur naturally in graphite during irradiation. By measuring the dimensional changes of the mechanically loaded samples to samples without a mechanical load applied, but receiving the same dose and temperature, the irradiation-induced creep levels for each type of graphite can be determined as a function of dose within each capsule at a uniform temperature. The key is to provide mechanically loaded and unloaded samples of the same graphite type with temperatures and dose levels as similar as possible. The structure of the graphite irradiation capsules are centered around this design requirement and attempt to provide samples experiencing the same temperatures and neutron dose levels as possible.

The Advanced Graphite Capsules (AGC) are used to irradiate graphite samples to the high temperature reactor conditions of the NGNP. The design of these capsules makes use of the symmetric neutron flux profile of the Advanced Test Reactor (ATR) to irradiate matched pairs of graphite samples above the reactor mid-point elevation that are mechanically loaded and below the reactor mid-point line that are not mechanically loaded during irradiation as shown in Figure 2. The design of the capsule and an insulating helium-argon cover gas mixture ensures a constant temperature for all samples throughout the capsule, but to ensure that sample matched pairs are similar in dose, the sample stacking order must be matched to the ATR flux profile such that similar samples on the top portion of the capsule match the sample dose received in the bottom of the capsule.

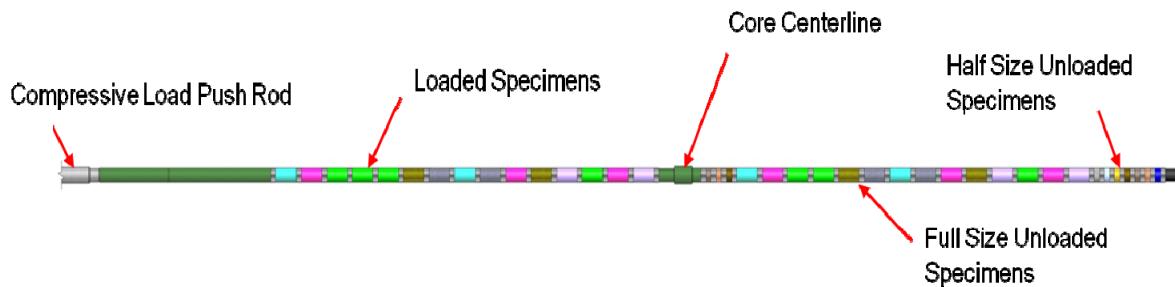

Figure 2. Schematic of AGC-1 capsule sample loading stack. Loaded samples are shown above the core centerline.

To achieve similar dose levels, the ATR flux profile is compared to the sample/capsule elevation specifications. By taking into account the flux profile, the samples are ordered so that matched pairs will receive similar dose levels on the bottom and top sections of the capsule. This stacking order is further complicated by the fact that the axial ATR neutron flux profile is not completely symmetric because of the core components slightly altering the profile as shown in Figure 3. This requires a small offset in the sample stacking order in the bottom half of the capsule to line up samples to the correct dose level. The offset is achieved by inserting a few smaller piggyback samples next to the core centerline of the capsule before the first creep sample. The creep samples can then be positioned as close as possible within the ATR neutron flux profile to achieve similar dose levels for each matched pair.

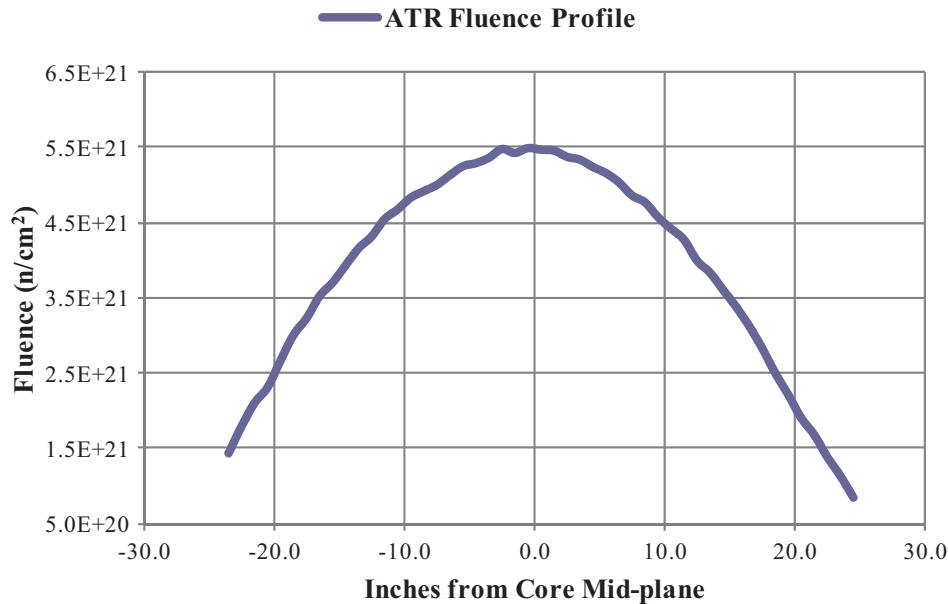

Figure 3. Fluence profile in ATR during AGC-1 capsule irradiation.

Because of the limited volume in the capsules and the large number of graphite types being investigated, the stacking order must ensure an equal distribution of samples over the entire dose range in the irradiation capsule. With six graphite types being investigated, three different mechanical load levels, and samples 25.4 mm long, a careful plan was required to evenly distribute as many samples as possible over the entire dose range. To gain more information for the newer graphite types, more samples of newer types were incorporated into the test train than older types (new PCEA graphite verses the old H451 type) somewhat skewing the number of samples slightly from type to type. Another consideration for the stacking order within the capsules is the microstructural orientation of the graphite samples to the applied load during irradiation. It is anticipated that with-grain creep rates differ from against-grain creep rates, and the with-grain creep is considered a more important parameter for nuclear graphite components so more samples in this orientation are required. Approximately 10–15% of the total samples are against-grain with the remaining being with-grain orientation.

Finally, the design has each capsule irradiated at a constant temperature, allowing only the dose and applied mechanical load to vary inside each capsule. The creep rate of graphite types is therefore assumed to be measured as only a function of load and dose within each capsule. To ascertain the temperature dependency of irradiation-induced material property changes, the creep rates of similar graphite type samples (at similar dose and load levels) must be compared between capsules. This implies that similar graphite types must be in the exact same locations in every capsule to receive similar dose and load levels at different temperatures. All six AGC capsules in the test series will be irradiated in the Idaho National Laboratory (INL) Advanced Test Reactor (ATR). AGC-1 and AGC-2 capsules were irradiated in the

south flux trap, AGC-3 will be irradiated in the east flux trap, and AGC-4 through AGC-6 capsules will be irradiated in the northeast flux trap to accommodate NGNP irradiation priorities. After irradiation, all AGC capsules will be cooled in the ATR Canal, sized for shipment, and shipped to the Materials and Fuels Complex where each capsule will be disassembled in the Hot Fuel Examination Facility (HFEF). During disassembly, the metallic capsule will be machined open and the individual samples removed from the interior graphite body containing the samples. Samples removed from the capsule will be loaded in a shipping drum and shipped to the INL Research Center (IRC) for PIE and storage for any future testing at INL's recently completed Carbon Characterization Laboratory (CCL) or ORNL's Low Activation Materials Development and Analysis (LAMDA) Laboratory shown in Figures 4 and 5.

Both the CCL and LAMDA facilities are designed to characterize and test low activated irradiated materials such as high-purity graphite, carbon-carbon composites, and silicon-carbide (SiC) composite materials.<sup>9</sup> The laboratories are fully capable of characterizing properties of both irradiated and nonirradiated materials, and will share the testing responsibilities for all AGC samples. The CCL will also process all specimens for initial visual inspections, dimensional measurements, and repackaging of samples (both pre- and post-irradiation) for storage or shipping, as shown in Figure 6.

Figure 5. ORNL's LAMDA Laboratory.

*Figure 6. The CCL glove box used to visually inspect irradiated graphite samples, perform dimensional measurement, and repackage samples for storage in the irradiated graphite vault located in Lab C-19.*

AGC-1 capsule irradiation and disassembly pre-irradiation examination of all AGC-1 samples was completed in July 2009. Sample loading and capsule insertion into the ATR occurred in August 2009. AGC-1 capsule irradiation began September 5, 2009, and was completed January 8, 2011, accumulating 351 effective full-power days of irradiation. AGC-1 was irradiated longer than originally planned, resulting in an accumulated dose range of from 1.36–6.94 dpa. After approximately 60 days of thermal cool-down, the top and bottom ends of the capsule were removed to allow the 42-inch-long sample section of the assembly to be inserted into a GE2000 shipping cask. The capsule was shipped to the Materials and Fuels Complex in April 2011, and disassembly was performed in the HFEF main cell from May through July 2011. Graphite samples were shipped to the IRC in June and July 2011, and PIE activities were initiated in July 2011.<sup>10</sup> Since the AGC-1 capsule was a first of its kind design, part of the function of the capsule was to determine the viability of these new designs and assumptions. No experiment works perfectly the first time and the AGC-1 capsule had some challenges as expected. The Technical and Functional Requirements<sup>11</sup> required a uniform temperature of 600°C (+/- 50°C) throughout the entire capsule and a maximum dose of 3.5 dpa. Because of an error in the heat transfer software, the temperature profile achieved during irradiation was not as uniform as designed as shown in Figure 7. The initial measured temperature levels achieved in reactor were approximately 195°C lower in both the upper and lower regions of the capsule than planned. As a consequence, it was decided to raise the temperature of the entire capsule to ~675°C on average by eliminating the conducting helium gas in the gas mixture. While this increased the overall temperatures of the samples, it also increased the uniformity of the temperature profile along the length of the capsule, which is the primary objective for each capsule. Maintaining 600°C temperature within the capsule is of minimal importance when compared to providing a uniform temperature throughout the capsule. However, a large amount of temperature control over the capsule was forfeited when the helium gas was eliminated. This allowed the reactor power levels during each cycle to have greater influence on the capsule temperatures than was originally planned.

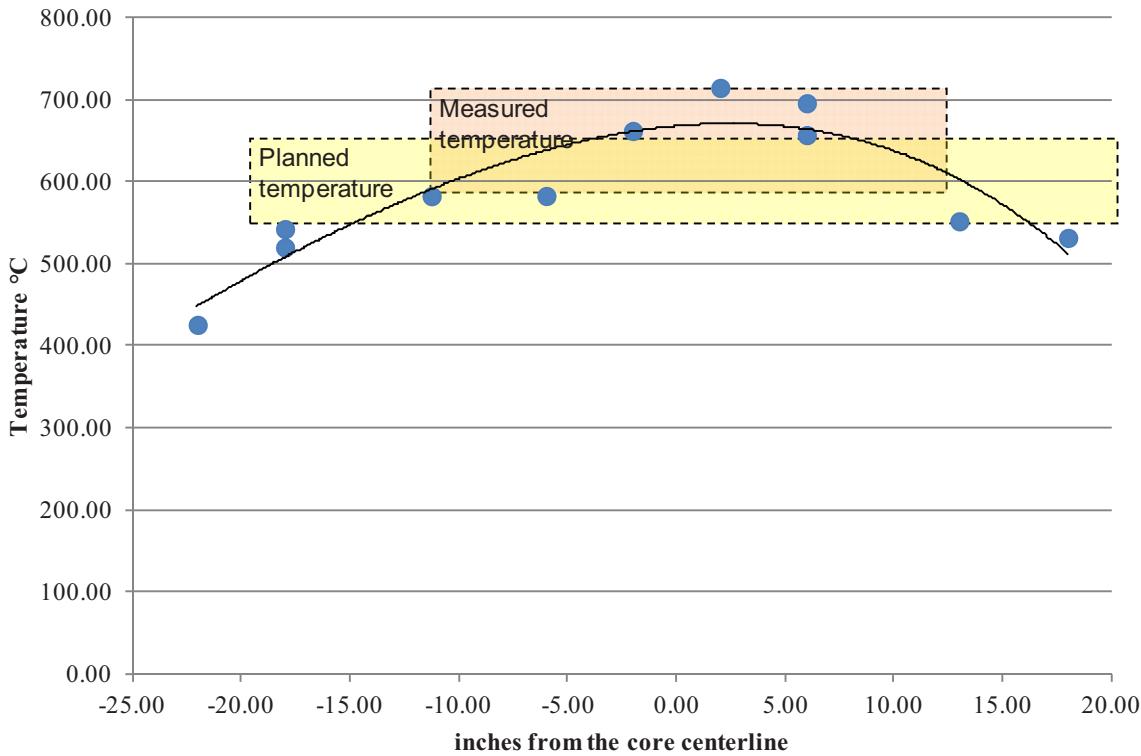

Figure 7. Preliminary estimate of achieved temperature profile in the AGC-1 capsule.

The AGC-1 capsule Technical and Functional Requirements targeted a maximum axial temperature variation of 100°C (+/- 50°C) and a maximum radial temperature variation of 40°C (+/- 20°C). During irradiation, the measured axial temperature variations were larger than planned but the radial variations were within acceptable levels for this first capsule (14°C difference at the cooler ends of the capsule to 59°C near the centerline of the capsule). The maximum measured and calculated axial temperature variation through the entire capsule was approximately 350°C with a dose ranging from 1.82–6.94 dpa.<sup>12</sup> However, the temperature variations in the creep sample region near the capsule centerline were much lower than over the entire capsule length (maximum temperature variation of 250°C), and over half of the creep samples were located near the middle 25-inches of the capsule centerline, which had a maximum temperature variation of only 130°C over this central length, bringing the variation near to acceptable levels as shown in Figure 7. The temperature variation between matched pair samples in this central 25-inch region ranged from a low of 30°C to a high of 68°C between sample pairs. While these temperature variations are higher than planned, they are within acceptable levels of uncertainty. Samples outside this central 25-inch region will need further analysis to determine how the larger temperature uncertainty affects the irradiation property changes.

Additionally, the received doses to the samples in the bottom part of the AGC-1 capsule were slightly different than designed. Prior to irradiation, an ATR flux profile was used to calculate the dose levels for each sample as a function of position within the AGC-1 capsule. The profile used was not the most current ATR flux profile and the positions of the unstressed (bottom) samples were not correctly calculated. Instead of a 44.5 mm (1.75 inch) offset from the reactor core centerline, an 88.9 mm (3.5 inch) offset was calculated. Based on the most current ATR flux profile, this increased offset generated a maximum 9.4% difference in received dose levels between the matched-pair samples at the start of irradiation in the AGC-1 capsule. However, by the end of the irradiation, with both capsule and sample shrinkage because of irradiation, the sample positions changed with the upper loaded samples getting closer to the core centerline. This migration of sample position resulting from irradiation brings the

matched pair samples back into alignment, reducing the maximum dose difference between matched-pair samples to an estimated 3–4%. This small dose difference will lead to an additional uncertainty in the received dose levels between matched pair samples and between similar sample types in different capsules. A more thorough analysis of these irradiation differences will occur in the final AGC-1 PIE report, which will include a complete analysis of all material property changes achieved for each sample, and a thorough analysis of any additional uncertainty resulting from these larger temperature and dose variations for each type of graphite. While the complexity of this first graphite capsule design prevented it from achieving the desired degree of test parameter control, the as-irradiated environmental conditions were accurately measured. These accurate capsule condition measurements will provide the data necessary to ascertain the material properties change for each individual sample within the final PIE report as well as the uncertainty within the specific material changes.

### **3. INITIAL POST-IRRADIATION EXAMINATION OF AGC-1 SAMPLES**

The AGC-1 samples are currently undergoing PIE at both of the INL and ORNL laboratories. At this time, approximately 25% of the PIE activity is complete with the remaining 75% of the work to be performed over the next 12 months. This is a significant endeavor. This data report provides a status on the progress of the PIE activity and presents dimensional change data for the AGC-1 samples.

#### **3.1 Measurement of Dimensional Change in AGC-1 samples.**

All AGC-1 samples were disassembled from the capsule and initially examined at the INL CCL [10]. All samples received from the INL's HFEF were visually inspected for damage, dimensionally measured, repackaged and stored in the INL's irradiated graphite storage vault. In February 2012, most of the large AGC-1 creep samples were shipped to Oak Ridge National Laboratory for remaining PIE as detailed in Table 1. The INL held back two creep samples from each graphite type to assist in qualifying the CCL for irradiation testing of the next capsule of AGC samples (AGC-2 capsule). These 12 samples at INL are also currently undergoing PIE.

**Table 1. Material property testing for AGC Graphite samples**

Physical Properties	Applicable Mechanisms and Models
Mass (bulk density)	Creep models, strength models, thermal models
Irradiation dimensional change	Dimensional change models, creep rate, mechanical property changes
Elemental impurities	Impurity induced oxidation, waste, and recycling
Elastic modulus	Creep models, strength models
Shear and Young's modulus	Creep models, strength models
Poisson's ratio	Creep models, strength models
Microstructure isotropy	Dimensional change mechanisms, texture effects, creep models
<b>Thermal properties</b>	
Coefficient of thermal expansion (25 to 800°C)	Gaps between core components, fluid dynamics, external stresses on components
Thermal diffusivity (25 to 1000°C)	Passive heat removal, fuel temperature
Specific heat (selective samples)	Passive heat removal, fuel temperature
<b>Mechanical Strength</b>	
Compressive, tensile, and flexural	Strength models, fracture toughness/failure criteria
Irradiation creep	Rate internal stresses are relieved, turnaround point, induced pore formation

Post-irradiation dimensional measurements were conducted on all AGC-1 samples during the receipt and visual examination of samples after disassembly. Dimensional measurements used ASTM International standard C 559 (10) to provide consistency with the pre-irradiation dimensional measurements. Dimensional change in each cylindrically shaped sample is measured in both the axial and radial directions. Four axial measurements, placed at 90-degree positions, are averaged together to arrive at the total axial length. The radial cross-section is taken at eight different locations down the length of the specimen to determine the average radial dimension for each sample as shown in Figure 8.

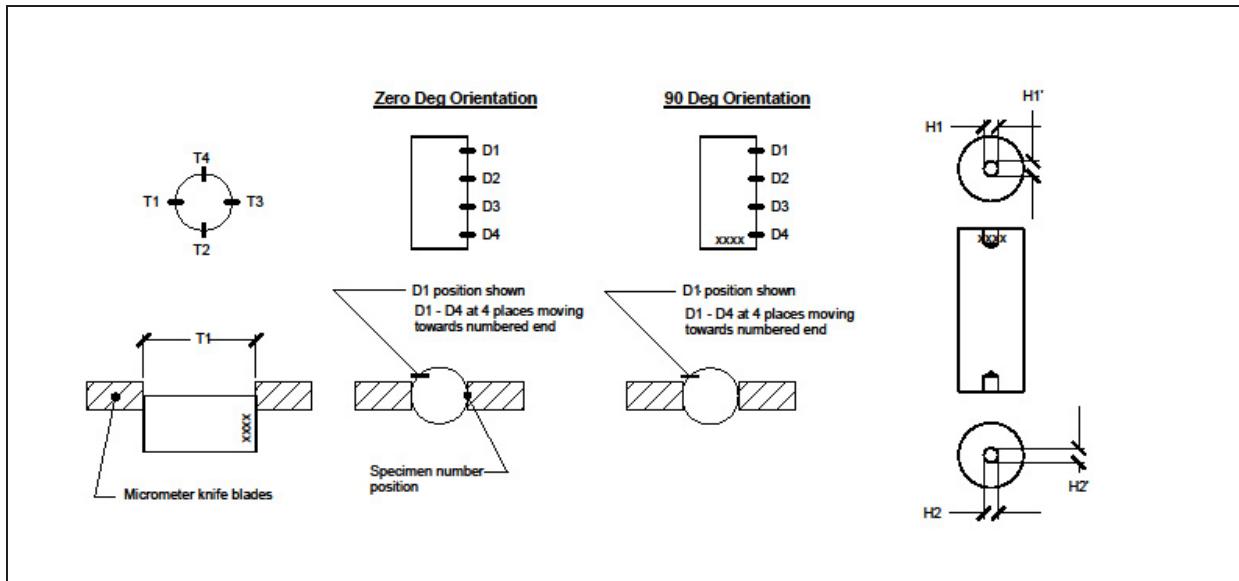

Figure 8. Schematic illustrating measuring points for dimensional measurement of large creep samples.

During irradiation, stressed samples with an applied compressive load will experience lateral creep (or barreling) due to Poisson's effect as shown in Figure 9 as well as more shrinkage from irradiation creep. Lateral creep in AGC-1 creep samples is determined by a comparison of the pre-irradiation and post-irradiation radial dimensions. However, the main focus for this report will be on axial dimensional changes (length changes) since the change is relatively large and requires minimum interpretation of the sample microstructure and grain orientation to ascertain the induced strain. Minimal lateral or volumetric creep results will be analyzed in this report but will be evaluated in the final AGC-1 PIE report.

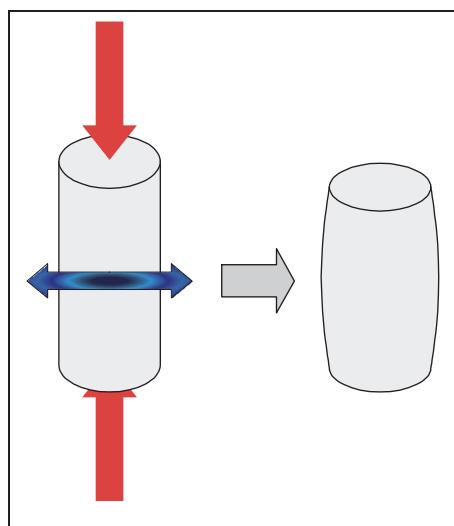

Figure 9. Schematic illustration of lateral creep (barreling) effect after irradiated compression testing.

The change in axial (length) dimensions for irradiated samples ( $\Delta L/L$ ) is derived from simply subtracting the length change values of the unirradiated creep samples from the irradiated sample dimensional values. Plotting the sample length change as a function of received dose provides the influence of the neutron dose on the irradiation-induced permanent strain in each sample. There is a clear

distinction between stressed and unstressed AGC-1 graphite samples, even when no other parameter is considered as shown in Figure 10. Unstressed samples underwent a dimensional change of 0–2% whereas stressed samples saw larger linear shrinkage between 0.5 and 6%. These simple results prove the dose and stress levels selected for the AGC test series were accurately estimated to induce significant irradiation dimensional change for all graphite types within the NGNP graphite operating temperature envelope.

While the sample type (creep or piggyback), type of graphite, different stress levels, and effects of temperature variations within the AGC-1 capsule have not yet been segregated from each other, the general behavior for all the graphite types is universal and within the expected levels predicted for the test series based on past irradiation experience of historic graphite types. As seen in Figure 10, all new or currently available nuclear graphite types have nominally the same irradiation response as the historic H451 type, indicating that the newly developed nuclear graphite types are well within the NGNP nuclear graphite requirements.

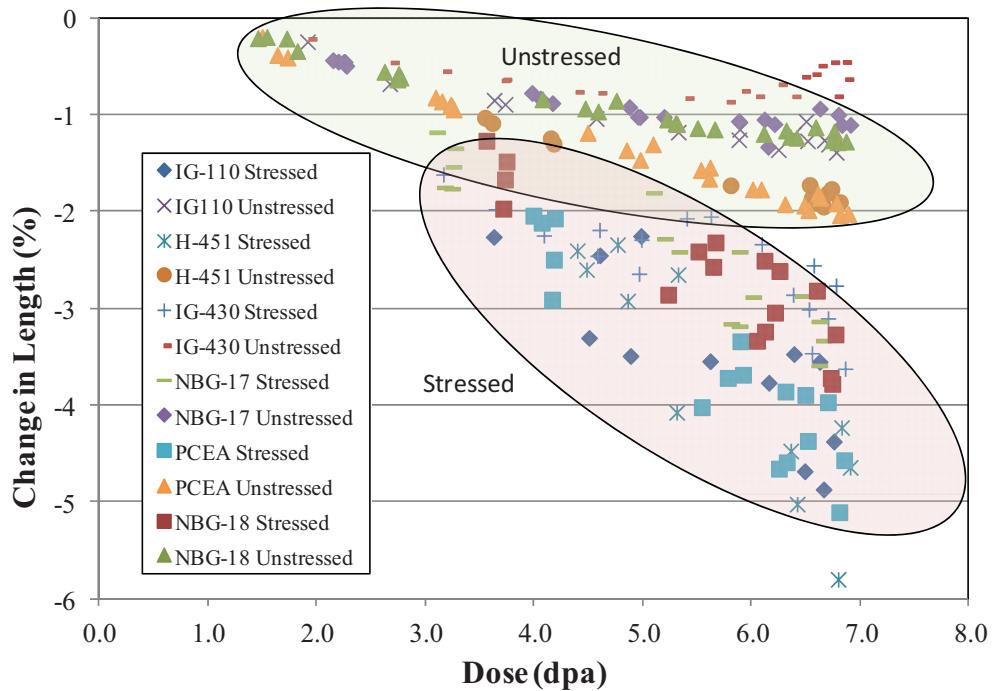

Figure 10. Change in sample length for all AGC-1 samples.

When data from only the creep samples are analyzed, some differences between graphite types are evident as shown in Figure 11. Even with the uncertainties identified previously, the unstressed length change for extruded graphite types is distinguishably larger than iso-molded or vibramolded graphite types. As seen in Table 2, this is not simply a difference in grain sizes or even coke source materials since the vibramolded NBG-18 material possesses the largest grain size (1.6 mm on average), the iso-molded IG-110 is formed with the smallest grain size (5–50  $\mu\text{m}$  on average), and the extruded PCEA has a moderate grain size (0.8 mm on average).

The data in Figure 11 has not differentiated the effects from applied load (induced stress) nor the individual sample temperatures. However, simply comparing the different levels of stress induced creep strain between the three forming methods shows differences between the extruded and isomolded graphite types. The dimensional change trends for vibramolded graphite types are difficult to analyze from this data, so additional testing parameters need to be accounted for to determine if any trends are apparent.

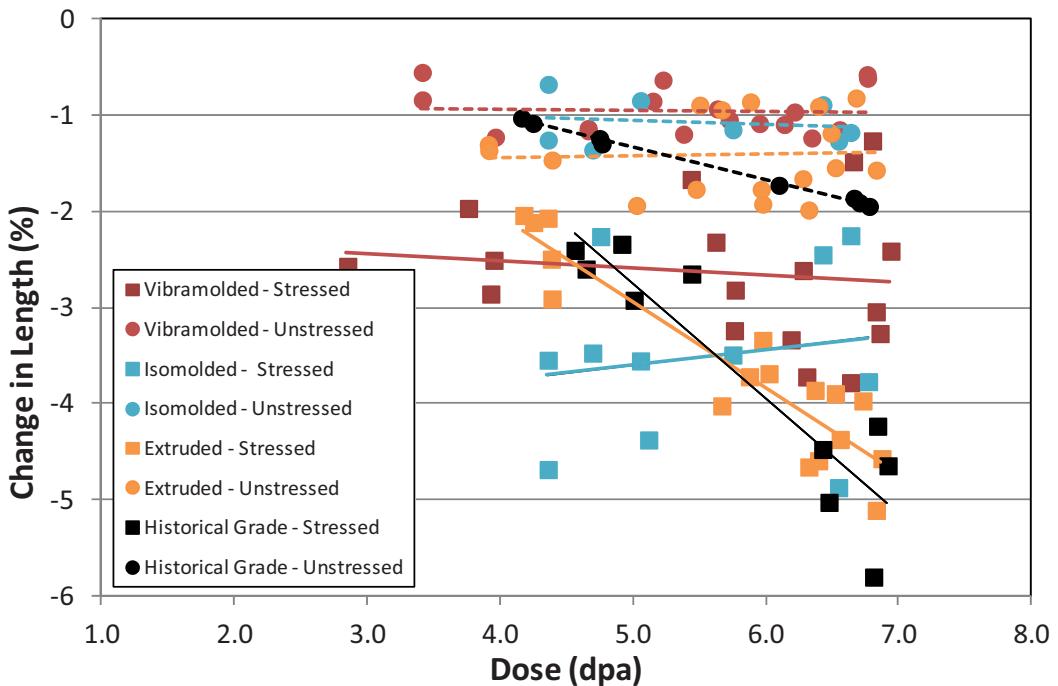

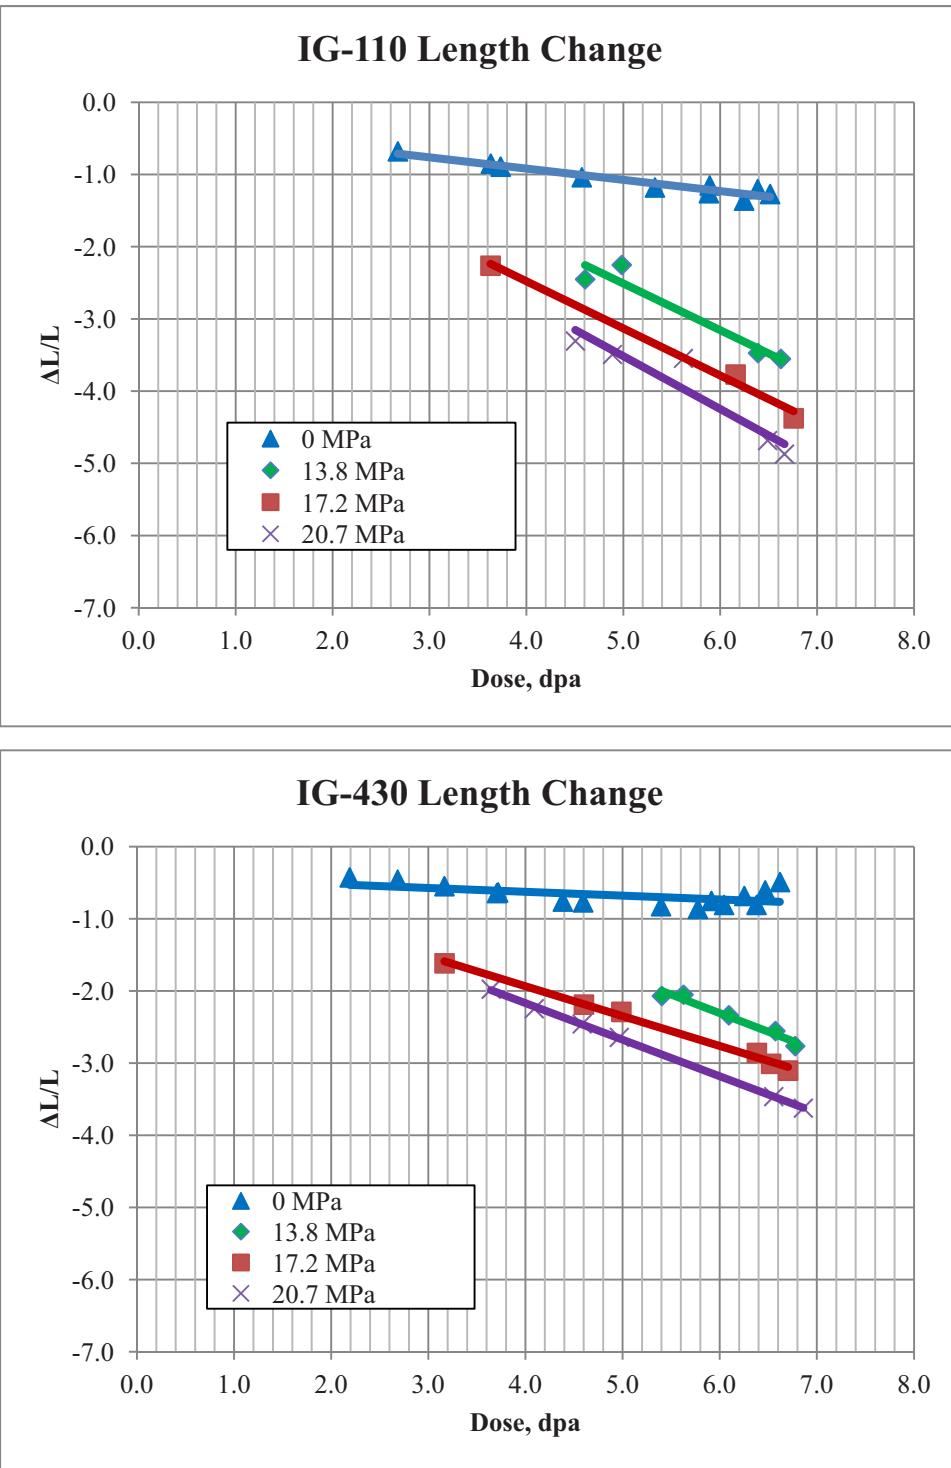

Figure 11. Differences in irradiation-induced length changes between the extruded, vibramolded, and isomolded graphite types for three different loading levels (14, 17, and 21 MPa).

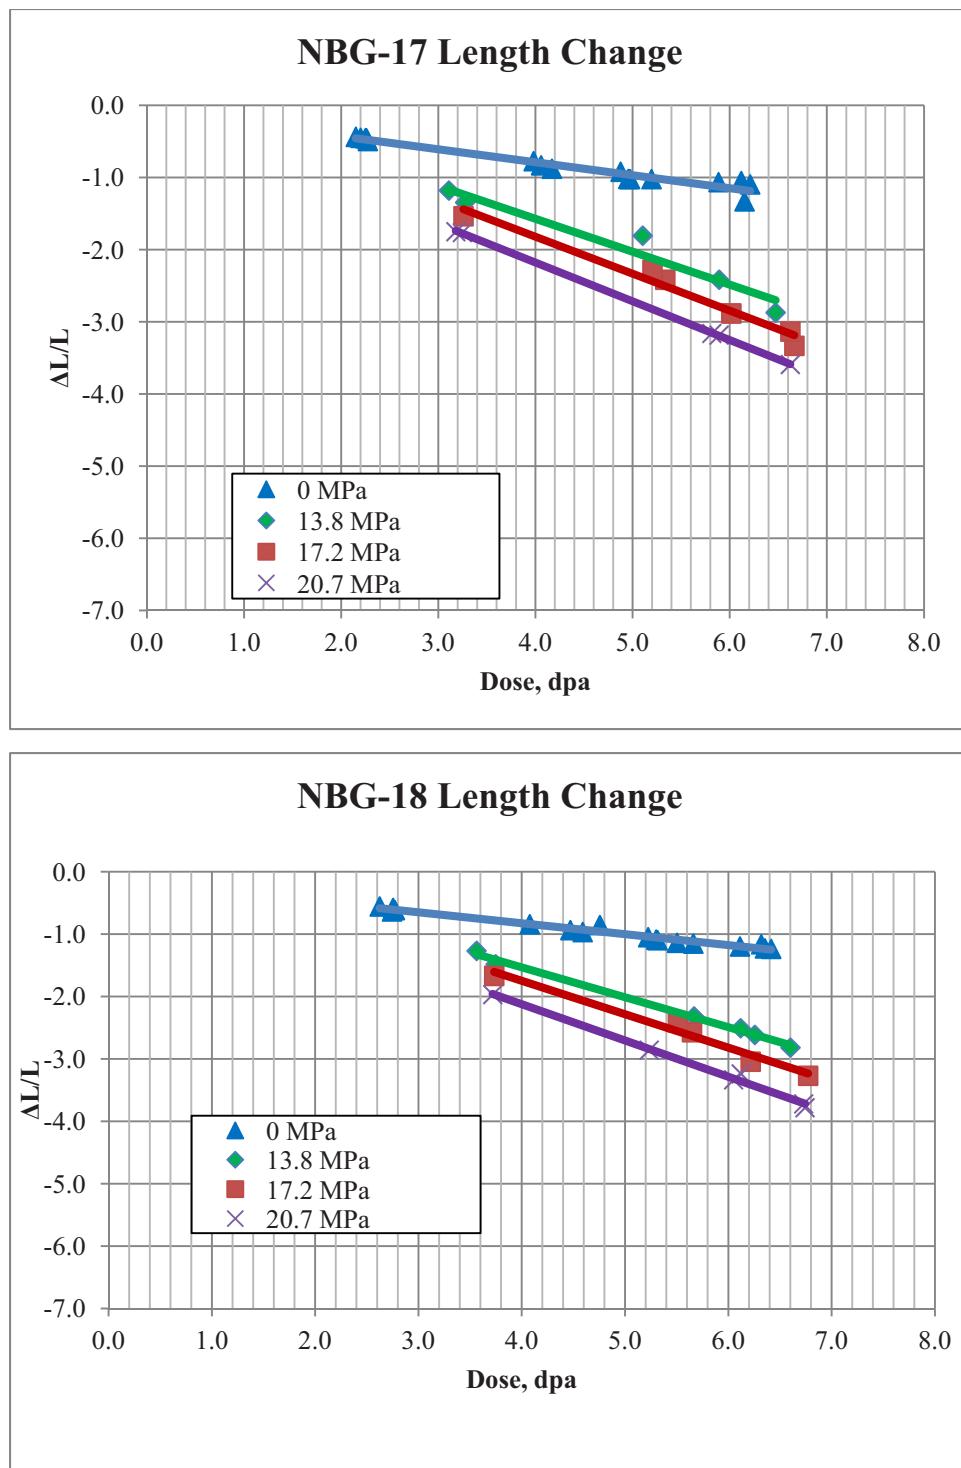

**Table 2. Major Types of AGC-1 graphite.**

Graphite	Manufacturer	Coke Type	Grain Size	Forming Process	Remarks
IG-110	Toyo-Tanso	Petroleum coke	Fine grain	Iso-molded	Prismatic fuel element, replaceable reflector, and core support pedestals
IG-430	Toyo-Tanso	Pitch coke	Fine grain	Iso-molded	Prismatic fuel element, replaceable reflector, and core support pedestals
NBG-18	SGL	Pitch coke	Medium grain	Vibramolded	Prismatic replaceable reflector Pebble bed reflector structure
NBG-17	SGL	Pitch coke	Medium grain	Vibramolded	Prismatic fuel element and replaceable reflector. Pebble bed reflector structure and insulation blocks
PCEA	GrafTech	Petroleum coke	Medium grain	Extruded	Prismatic fuel and replaceable block. Pebble bed reflector and insulation blocks
H-451	SGL	Petroleum coke	Medium grain	Extruded	Historical reference, no longer available.

Dimensional length changes for the six major types of graphite at the four applied loads (0, 13.8, 17.2, and 20.7 MPa) are presented for each type of graphite in Figures 12, 13, and 14. Some trends are easily seen from the data. For example, samples for all graphite types with higher applied loads show an accelerated dimensional change for the same received dose levels. It is also interesting to note that all new graphite types appear to have lower dimensional changes under stress than the historic H451 graphite grade. However, this result will require further analysis in the final AGC-1 PIE report following completion of post-irradiation testing. The final PIE report will establish levels of confidence for the temperature, dose, and applied loads for each of the samples during analysis. Based on these confidence levels, the accuracy of the data analysis will be determined within the final report.

*Figure 12. Irradiation-induced length change for isomolded graphite types at three different loading levels (IG-110 & IG-430).*

*Figure 13. Irradiation-induced length change for vibramolded graphite types at three different loading levels (NBG-17 & NBG-18).*

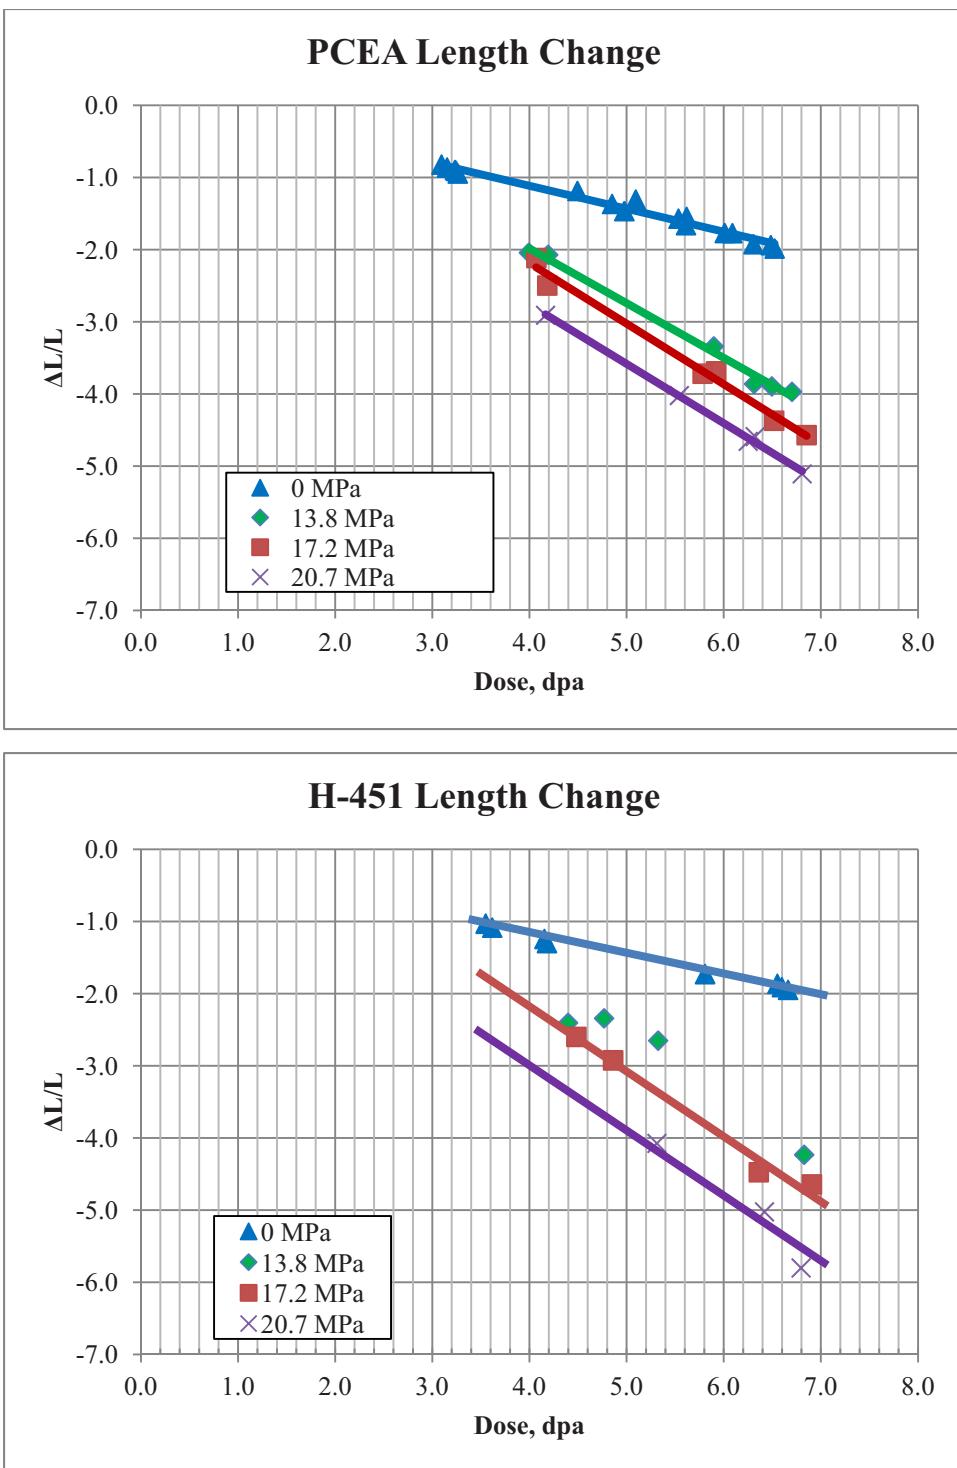

Figure 14. Irradiation-induced length change for extruded graphite types at three different loading levels (new PCEA & historic type H451).

The unstressed irradiation-induced dimensional change was measured for the A3 TRISO fuel compact matrix material and other minor graphite types as shown in Figures 15 and 16. The A3 compact matrix samples show dimensional growth/expansion at higher levels of neutron dose. Dimensional expansion past the original component dimensions is generally considered undesirable in a nuclear reactor and should be avoided. This undesirable behavior is most likely because of the relatively low A3 matrix fabrication temperatures of 1800°C, which is not enough to fully graphitize the carbon-rich compact material. Past experience and studies have shown that a component with a fully graphitic carbon structure provides greater stability under neutron irradiation. To provide maximum irradiation stability, nuclear grade graphite is fully graphitized at 2800–3000°C.

None of the minor graphite types exhibited dimensional increase over the AGC-1 dose range, illustrating the irradiation dimensional stability of nuclear grade graphite as shown in Figure 16. The unstressed dimensional changes for these minor types were comparable to the unstressed change for the major graphite types presented previously; -1 to -2% shrinkage. A summary of PIE dimensional change data measured for all AGC-1 samples is presented in Appendix A. The table includes dimensional length change measurements as well as lateral (diameter) dimensional (both measured in millimeters) and volumetric changes for each sample. This data will be presented within the final AGC-1 PIE report after a full analysis of all testing and measurements has been completed.

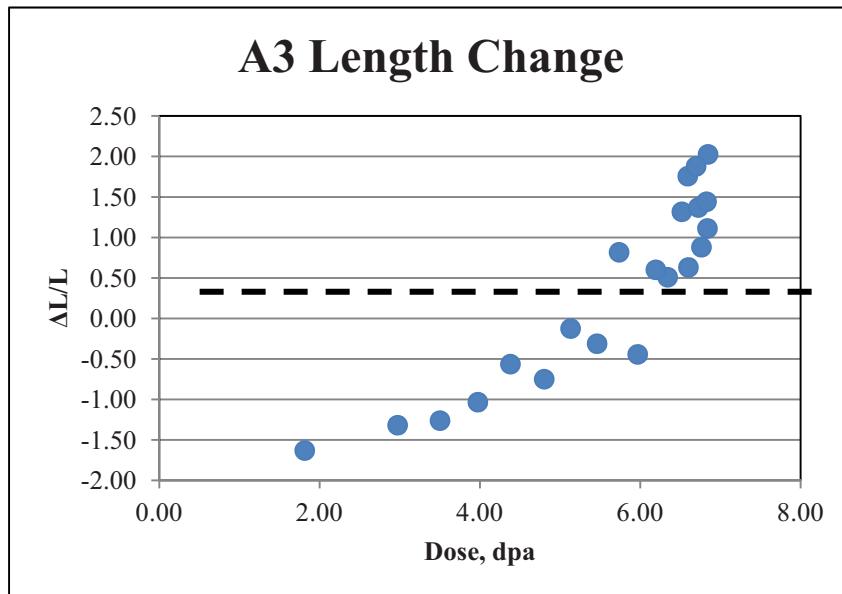

Figure 15. Irradiation-induced length change for A3 compact matrix material showing length expansion past the original (unirradiated) component length.

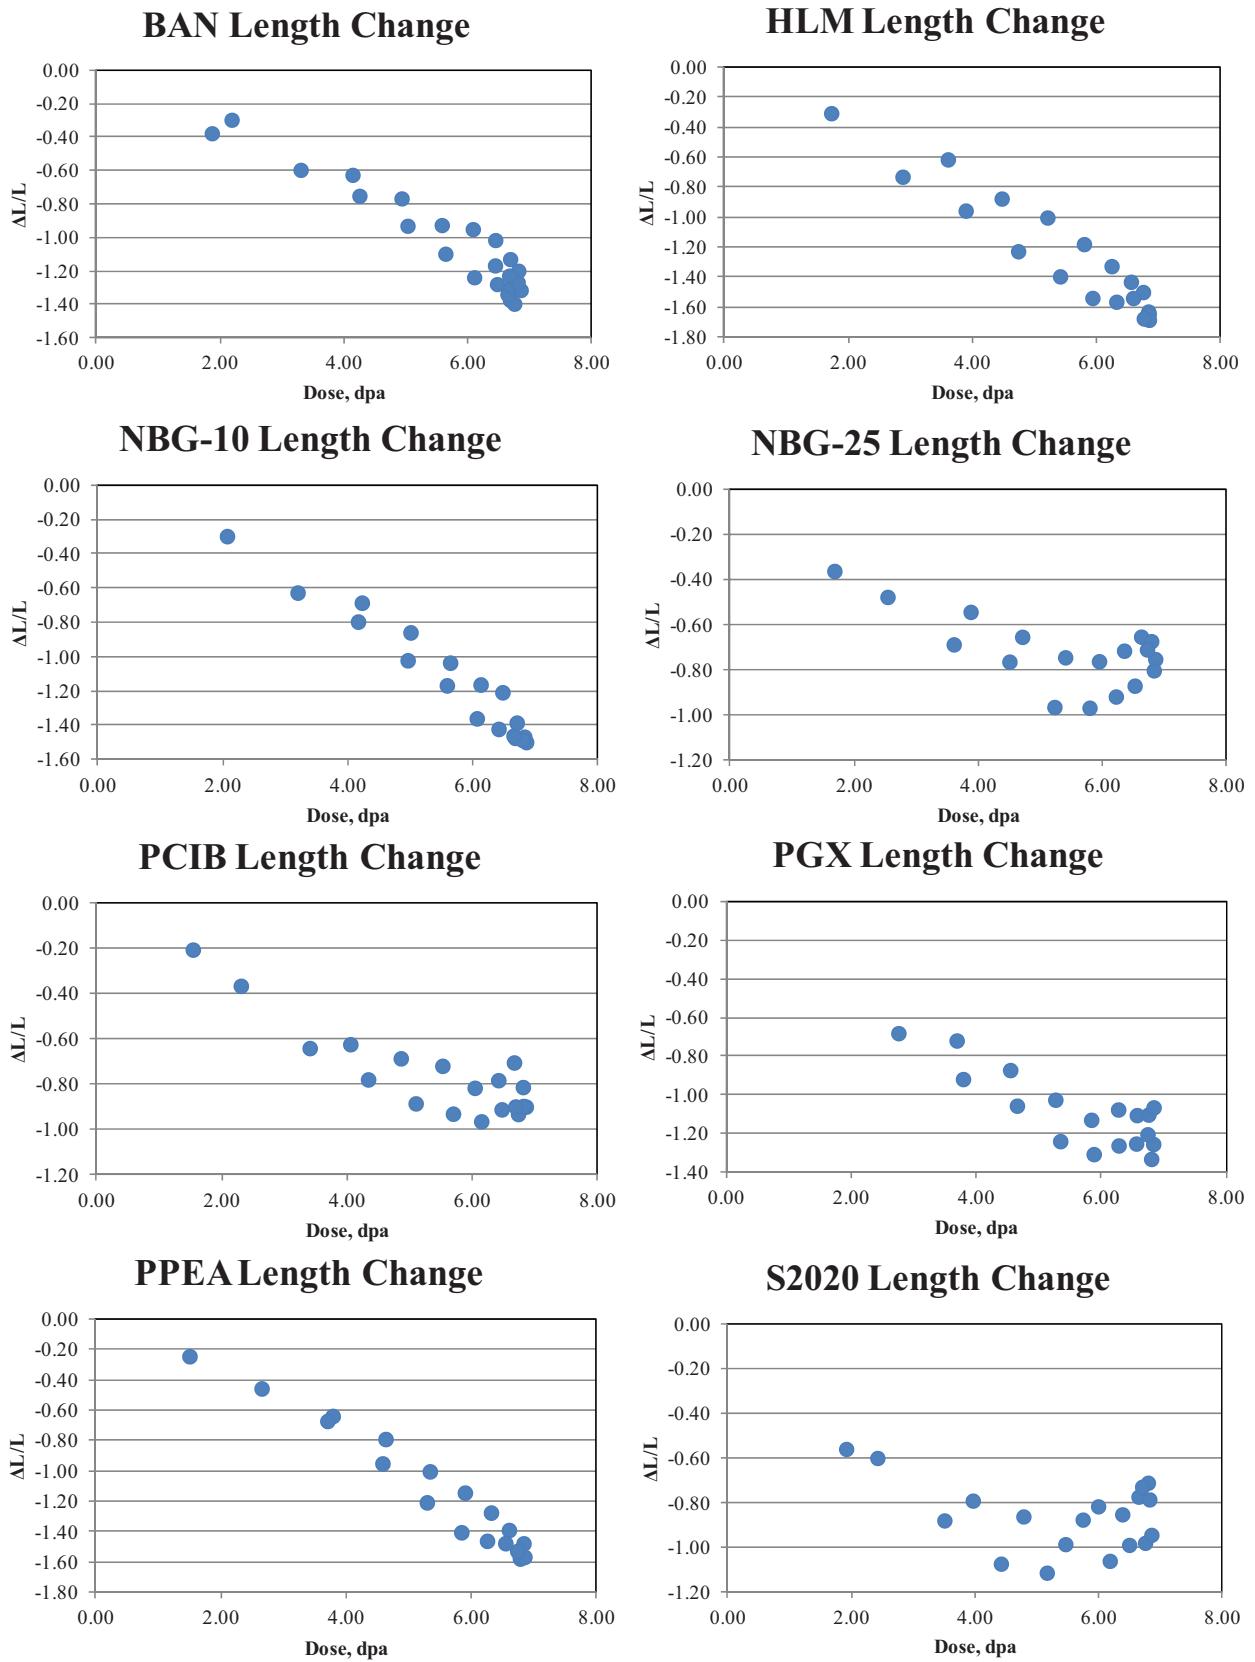

Figure 16. Irradiation-induced length change for minor graphite types in AGC-1 capsule.

Specimens were lost prior to post irradiation measurements. Post Irradiation dimensions were estimated using distance and % length change values from other specimens of same grade.						
CAN specimens. Preirradiation lengths were taken as nominal. Post irradiation dimensions were estimated using distances and % length change of NBG-25 specimens in the center channel.
