ABSTRACT

This paper presents the characterization of potential feed for processing relatively low radioactive waste tanks. The feed characterization is based on waste characterization data extracted from the waste characterization system. This data is compared to salt cake sample results from Tanks 37, 38 and 41.

Feed Basis for Processing Relatively Low Radioactivity Waste Tanks

By M. D. Drumm

1 Introduction

To prepare cesium (Cs) for final disposal, it is necessary to separate Cs and other soluble transuranic material from the waste stream. The original baseline salt processing step at SRS, known as In-Tank Precipitation (ITP), initiated operation in September 1995. During operations, benzene (a flammable gas) evolved from the process at higher rates than expected.

In August 1996, the Defense Nuclear Facilities Safety Board (DNFSB) issued Recommendation 96-1 that operations and tests in the ITP Facility not proceed without an improved understanding of the mechanisms of benzene generation, retention, and release. Extensive laboratory studies conducted from December 1995 through January 1998 ultimately concluded that production goals and safety requirements could not be simultaneously met in the ITP Facility, as configured. This resulted in a Westinghouse Savannah River Company (WSRC) recommendation to the Department of Energy in January 1998 to suspend ITP operations and conduct a systems engineering evaluation of salt disposition options and to recommend the preferred alternatives.

DOE designated a preferred alternative, Caustic Side Solvent Extraction, in October 2001. As described in the Salt Processing EIS Record of Decision (ROD), DOE plans to pursue a variety of methods to disposition the salt waste. These are:

- Low Curie Salt Waste to Saltstone
- Actinide Removal from Low Curie Waste followed by Disposal in Saltstone
- Actinide Removal followed by future treatment of the resulting stream rich in Cs
- Caustic Side Solvent Extraction

This paper presents the characterization of potential feed for processing relatively low radioactive waste tanks. The feed characterization is based on waste characterization data extracted from the Waste Characterization System (WCS). This data is compared to salt cake sample results from Tanks 37, 38 and 41. Any revisions to the expected feed will be represented by revisions to this document.

2 Approach

Salt cake in High Level Waste (HLW) tanks consists of crystallized salts with interstitial void space and entrained insoluble solids assumed to be sludge solids. In order to determine the composition of the salt cake, the individual parts (saltcake, interstitial supernate, and entrained sludge) are first identified and then combined in the appropriate ratios to formulate the final characterization.

The interstitial space is assumed to consist of gas and supernate. Prior to dissolving the salt cake, the interstitial space is assumed to be drained such that 30% liquid supernate remains. Such drainage is possible in a laboratory test on simulated salt cake in a small scale tank.¹ Hydraulic modeling of a full-scale tank indicates the same may be possible at full-scale.² The total interstitial liquid volume is assumed to be 22%.³

Chemical and Radionuclide concentrations for salt cake and supernate in each waste tank with salt cake are extracted from the HLW Waste Characterization System (WCS)³ or calculated from the information given in the WCS. WCS indicates radionuclides are assumed to be in the interstitial supernate and entrained insoluble solids and not in the saltcake solids.

The waste tanks deemed relatively low in activity are assumed to be processed by two options: treatment by actinide removal at 512-S (formerly Late Wash) or sending the dissolved salt to Tank 50 to be processed by Saltstone with only chemical adjustment to meet the Saltstone chemical concentration requirements.

For the tanks being treated by the Actinide Removal Process (ARP) the chemical and radionuclide data are adjusted to a sodium concentration of 6.44 M by two different methods, simulating dissolution with inhibited water (0.01 M NaOH/0.011 M NaNO₂) and simulating dissolution with DWPF recycle. The DWPF recycle is assumed to be characteristic of Tank 22 supernate.

For tanks being treated by the Low Curie Salt (LCS) process, the chemical and radionuclide data are adjusted assuming two different scenarios. In both scenarios, the chemical and radionuclide data are adjusted to a sodium concentration of 7.4 M by simulating dissolution with inhibited water. The dissolved 7.4 M salt solution is then adjusted to a sodium concentration of 6.0 M assuming two different mediums, inhibited water and DWPF recycle. The DWPF recycle is assumed to be characteristic of Tank 22 supernate.

The radionuclide contribution of the insoluble solids is estimated from the average distribution of radionuclides in HLW sludge, which is extracted from the WCS. The radionuclide contribution range of sludge is then calculated by multiplying the mass-based distribution by 600 mg of sludge solids per liter of 6.44 M salt solution for the ARP feed and 300 mg of sludge solids per liter of 6.0 M salt solution for LCS.³ The sludge contribution is then added to the supernate contribution estimated above.

3 Salt Cake and Feed Solution Characterization

Waste tanks with Salt cake include Tanks 1, 2, 3, 9, 10, 25, 27, 28, 29, 31, 33, 34, 36, 37, 38, 41, 44, 45, 46, and 47. Tanks 1, 2, 3, 9, and 10 do not have transferable free supernate, so no recent supernate sample data is available to adequately characterize the radionuclide inventory. The lack of current information on the composition of the supernate in these waste tanks should be considered when using any of the available data for these tanks. The tanks to be treated by LCS are Tanks 9, 10, 29, 31, 36, 37, 38, and 41. The waste tanks treated by ARP are Tanks 1, 2, 3, 25, 27, 28, 33, 34, 44, 45, 46, and 47.

Table 1 shows the salt cake composition as calculated from the information given in the WCS. WCS lists only two compositions for salt cake, one for F-Area salt waste and one for H-Area salt waste, thus, Table 1: Salt Cake Composition shows tanks in F-Area have the same saltcake composition and the tanks in H-Area have the same saltcake composition. Table 2 shows the supernate composition per tank extracted from WCS and converted to a consistent set of units. Table 3 shows the average composition of sludge from WCS. Average sludge composition is estimated by dividing the total of each component by the total mass of sludge in both tank farms as reported by WCS. Table 4 shows the supernate composition of Tank 22 supernate that is assumed to be the composition of DWPF recycle. Table 5 and Table 6 show the estimated compositions of the feed material produced from the ARP waste tanks after adjusting the drained saltcake to a sodium concentration of 6.44 M with inhibited water (0.01 M NaOH) and DWPF recycle, respectively. Table 7 shows the estimated compositions of feed material from LCS waste tanks after dissolution with inhibited water to a sodium concentration of 7.4 M, and adjustment to a 6.0 M sodium concentration using inhibited water. Table 8 shows the estimated compositions of feed material from LCS waste tanks after dissolution with inhibited water to a sodium concentration of 7.4 M and adjustment to a 6.0 M sodium concentration using DWPF recycle.

Table 9, Table 10, Table 11 and Table 12 show the total estimated volume of salt solution produced after dissolution and chemical adjustment of each of the four scenarios. To account for the non-ideal solution, the specific gravity of the dissolved salt solution was calculated based on the sodium concentration.⁴ The amount of dilution water required to give a final dissolved salt solution sodium concentration of 6.44 M was then determined algebraically.

$$\rho_{ss} = (1.009 + 0.04454 * [\text{Na}]_{ss}) * 8.34 \quad (1)$$

$$\rho_{ss} = m_{ss} / V_{ss} \quad (2)$$

$$m_{ss} = m_{ds} + m_{H2O} \quad (3)$$

Combining equations 2 and 3 and equating them to equation 1, yields

$$(m_{ds} + m_{H2O})/V_{ss} = (1.009 + .04454 * [Na]_{ss}) * 8.34 \quad (4)$$

$$m_{H2O} = V_{ss} * [(1.009 + .04454 * [Na]_{ss}) * 8.34] - m_{ds} \quad (5)$$

$$V_{ss} = [Na]_{ds} / [Na]_{ss} * V_{ds} \quad (6)$$

Inserting equation 6 into equation 5 yields

$$m_{H2O} = [Na]_{ds} / [Na]_{ss} * V_{ds} * [(1.009 + .04454 * [Na]_{ss}) * 8.34] - m_{ds} \quad (7)$$

$$V_{H2O} = m_{H2O} / \rho_{H2O} \quad (8)$$

Combining equations 7 and 8 yield

$$V_{H2O} = \{ [Na]_{ds} / [Na]_{ss} * V_{ds} * [(1.009 + .04454 * [Na]_{ss}) * 8.34] - m_{ds} \} / \rho_{H2O} \quad (9)$$

ss = salt solution after dilution

ds = drained salt

H₂O = dilution water

ρ = density (lb/gal)

[Na] = sodium concentration (M)

V = volume (gal)

m = mass (lb)

Appendix A contains total gamma data from the Tank Chemistry Database, which provides a comparison of current cesium values in WCS to historical analysis.

Notes:

- Sr/Y concentrations are extracted from reference 5 due to limited data within WCS.
- Cs concentrations were converted to Ci/gal from the Cs concentrations in mg/L given in WCS, using a Specific Activity of 8.70 E-2 Ci/mg.
- Ba-137m concentrations assumed to be 94.6% of the Cs-137 concentration.

Notes:

- Sr/Y concentrations are extracted from reference 5 due to limited data within WCS.
- Cs concentrations were converted to Ci/gal from the Cs concentrations in mg/L given in WCS, using a Specific Activity of 8.70 E-2 Ci/mg.
- Ba-137m concentrations assumed to be 94.6% of the Cs-137 concentration.

4 Real Waste Salt Cake Samples

Since 1994, several salt cake samples were extracted from Tanks 37, 38, and 41.^{6,7,8} These samples were obtained using a sampling cup that is driven into the surface of the salt cake. The material is held in the cup primarily by friction, but is aided by a retaining ring in some cases. These samples are nominally about 50 ml each. Though not necessarily representative of the entire tank contents, these samples offer significant insight to the composition of the salt cake. The results from these samples are presented as if the material is dissolved and diluted with water to 6.44 M total sodium concentration. The composition predicted by WCS is presented in the adjacent column for comparison.

The WCS predicted composition assumes 70% drainage of interstitial liquid. Additional projections are provided if better drainage can be achieved. However, the samples from all three tanks were not drained to a specified supernate level. The sample technique compresses the salt cake, which forces out interstitial liquid. As the sample is removed from the tank, the remaining interstitial liquid is allowed to drain from the sample before packaging and shipping to the laboratory. If possible, the void fraction is estimated for each sample along with an estimate of retained supernate.

The weight fraction of supernate can be calculated as follows:

$$\begin{aligned} w_{\text{supr}} &= M_{\text{supr}}/M_{\text{bulk}} = M_{\text{H}_2\text{O}}/(w_{\text{H}_2\text{O-sup}} * M_{\text{bulk}}) \\ &= w_{\text{H}_2\text{O-bulk}}/w_{\text{H}_2\text{O-sup}} \end{aligned} \quad (10)$$

where

- M_{supr} = mass of supernate in sample
- M_{bulk} = mass of sample
- $M_{\text{H}_2\text{O}}$ = mass of water in sample
- v_{supr} = the volume fraction of the supernate in the sample
- $w_{\text{H}_2\text{O-bulk}}$ = the weight fraction of the water in the sample
- $w_{\text{H}_2\text{O-sup}}$ = the weight fraction of the water in the supernate, and
- w_{supr} = the weight fraction of supernate in the sample.

The volume fraction of supernate in the sample can be calculated as follows:

$$\begin{aligned} v_{\text{supr}} &= V_{\text{supr}}/V_{\text{bulk}} = (M_{\text{supr}}/\rho_{\text{supr}})/(M_{\text{bulk}}/\rho_{\text{bulk}}) \\ &= (M_{\text{supr}}/M_{\text{bulk}})*(ρ_{\text{bulk}}/ρ_{\text{supr}}) \\ &= w_{\text{supr}}*(ρ_{\text{bulk}}/ρ_{\text{supr}}) \end{aligned} \quad (11)$$

where

- ρ_{supr} and ρ_{bulk} = the densities of the supernate and bulk sample respectively.

Equation 10 is combined with equation 11 to yield

$$v_{\text{supr}} = (w_{\text{H}_2\text{O-bulk}}/w_{\text{H}_2\text{O-sup}})*(ρ_{\text{bulk}}/ρ_{\text{supr}}) \quad (12)$$

By analogy to equation 12,

$$v_{\text{salt}} = w_{\text{salt}} * (ρ_{\text{bulk}}/ρ_{\text{salt}}) \quad (13)$$

where

v_{salt} = the volume fraction of the salt in the sample, and

ρ_{salt} = the density of the salt.

Since $w_{supr} + w_{salt} = 1$, neglecting the contribution of air, then

$$v_{salt} = (1-w_{supr}) * (\rho_{bulk}/\rho_{salt}) \quad (14)$$

Combining equation 10 with equation 14 results in

$$v_{salt} = (1-w_{H2O-bulk}/w_{H2O-sup}) * (\rho_{bulk}/\rho_{salt}) \quad (15)$$

The volume fraction of air in the bulk sample was assumed to be the balance of the sample volume. The void fraction is the fraction of sample volume not occupied by salt or $v_{supr} + v_{air}$. Using the sample density and weight fraction water data in Table 13 and assuming the crystalline solids density is 2.2,³ the calculated sample void fractions are 0.59, 0.41, and 0.42 for the Tank 37, 38, and 41 samples respectively.

Samples from all three tanks show much higher total insoluble solids than is predicted. These high insoluble solids content may be due to solids settling from the free supernate over a long period. Waste is not routinely transferred from or to these tanks. After long periods of stagnation, fine particles may settle as well as dust and corrosion debris. Aluminum precipitation as gibbsite and sodium aluminosilicates is known to occur slowly. All these mechanisms can contribute to the unusually high insoluble content of these samples.
