## **EXECUTIVE SUMMARY**

The River Protection Project (RPP) – Hanford Waste Treatment and Immobilization Plant (WTP) is to prepare and process High Level Waste (HLW) streams into glass waste forms that will meet HLW disposal requirements. Samples of HLW sludge and samples of this sludge mixed with glass-forming chemicals are to be taken and analyzed for process control. Glass characterization from the melter is not included in the scope. The development of viable analytical protocols to provide the required elemental analyses of these samples with rapid turnaround times (before and after addition of the glass-forming chemicals) has been defined as an RPP statement of work for the Analytical Development Section (ADS) of the Savannah River National Laboratory (SRNL). Wet chemistry is serving as the baseline comparison to laser ablation for method development.

One of the simulants used in this study by ADS was AY-102/C-106 melter feed slurry simulant, a simulant used to represent HLW samples after the addition of glass-forming chemicals. Several different dissolution methods were used by ADS in preparing samples of this simulant for elemental analyses by inductively coupled plasma-atomic emission spectroscopy (ICP-AES). The measurements generated by this process were provided to SRNL's Statistical Consulting Section (SCS) for analysis.

The measurement data generated for samples of the RPP-WTP AY-102/C-106 melter feed slurry simulant are presented in this report and the different approaches used to prepare the samples are statistically compared. Comparisons among three of the dissolution methods are highlighted in this analysis. The methods are: sodium peroxide fusion in nickel crucibles, acidification with  $\text{HNO}_3/\text{HCl}$  at room temperature, and cesium carbonate fusion in zirconium crucibles. A summary table of the measurement averages generated by the three methods is presented. The cesium carbonate fusion method yielded measurements with significantly different mean values from the other two preparation methods for several of the elements.

This report is being provided for informational purposes and supplements the technical report by Coleman and Edwards, “SRNL Phase I Tests of Wet Chemical Non-Dilute/ICP-AES Elemental Analysis Methods for Simulated HLW 2A and HLW 2B Hanford Waste Treatment Plant Samples – Interim Report,” WSRC-TR-2005-00169, SRNL-RPP-2005-00023.

## **1.0 INTRODUCTION AND BACKGROUND**

The River Protection Project (RPP) – Hanford Waste Treatment and Immobilization Plant (WTP) is to prepare and process Hanford High Level Waste (HLW) streams into glass waste forms that will meet HLW disposal requirements. The Pretreatment Facility will transfer the HLW to the Melter Feed Preparation Vessel (MFPV) in the vitrification facility as part of this process. In the MFPV, the HLW sludge is to be blended with glass-forming chemicals to produce slurry that is an acceptable melter feed. Variations in the sludge retrieval, pretreatment, and vitrification processes will cause deviations in the nominal melter feed compositions and resulting glass chemistry. Samples of the MFPV are to be taken and analyzed to assess the extent of the deviations in the nominal melter feed. Specifically, MFPV samples are to be taken for each HLW batch transferred to this tank before the addition of the glass-forming chemicals; the samples are to be analyzed; the analytical results are to be used to guide the addition of the glass-forming chemicals; and after their addition, another set of MFPV samples is to be taken and analyzed. This final set of analytical measurements is to serve as the basis for the acceptance of the MFPV contents for transfer to the melter. Samples have to be analyzed and the results reported within 9 hours to ensure that feed is available to the melter. The development of viable analytical protocols to provide the required elemental analyses of these MFPV samples (before and after addition of the glass-forming chemicals) with rapid turnaround times has been defined as an RPP statement of work [1] for the Savannah River National Laboratory (SRNL). The characterization of the glass waste form produced by the melter is not included in the scope of this work.

In accepting this work, SRNL's Analytical Development Section (ADS) issued a Task Technical and Quality Assurance Plan [2] that covered a set of activities that were to be conducted by ADS using simulants previously prepared for the RPP-WTP program as the first phase (Phase I) of study. One of the simulants was melter feed slurry containing AY-102/C-106 simulant with glass-forming chemicals. Different dissolution methods were used by ADS in preparing samples of this simulant (on a dried solids and a vitrified solids basis) for elemental analyses by inductively coupled plasma-atomic emission spectroscopy (ICP-AES). Wet chemistry is serving as the baseline comparison to laser ablation for method development. The measurements generated by this process were provided to SRNL's Statistical Consulting Section (SCS) for analysis.

The purpose of this technical report is to present a statistical interpretation of the analytical data generated by ADS and provide a comparison of the results. This report is being provided for informational purposes and supplements the technical report by Coleman and Edwards, "SRNL Phase I Tests of Wet Chemical Non-Dilute/ICP-AES Elemental Analysis Methods for Simulated HLW 2A and HLW 2B Hanford Waste Treatment Plant Samples – Interim Report," WSRC-TR-2005-00169, SRNL-RPP-2005-00023. The statistical analyses were carried out using JMP® Version 5.1.2 [3] from SAS Institute, Inc. The validation and verification for this statistical software is provided in [4].

## **2.0 RESULTS**

In this section the measurement data generated for samples of the RPP-WTP AY-102/C-106 melter feed slurry simulant are presented and the different approaches used to prepare the samples are statistically compared. A summary table of three of the dissolution methods used to analyze the samples of this material on a dried-solids basis is highlighted in the discussion that follows.

## **2.1 A Description of the Measurement Data**

The measurement data from this ADS study are provided in Table A1 and Table A2 in the Appendix. Two tables are used to cover all of the elemental analyses that were recorded during this investigation. Table A1 provides elemental concentrations in parts per million (ppm) for the following elements: silver (Ag), aluminum (Al), boron (B), barium (Ba), calcium (Ca), cadmium (Cd), cerium (Ce), copper (Cu), iron (Fe), potassium (K), lanthanum (La), lithium (Li), magnesium (Mg), manganese (Mn), and molybdenum (Mo). Table A2 provides elemental concentrations in ppm for the following elements: sodium (Na), nickel (Ni), phosphorous (P), lead (Pb), sulfur (S), antimony (Sb), silicon (Si), tin (Sn), strontium (Sr), thorium (Th), titanium (Ti), tellurium (Tl), uranium (U), yttrium (Y), zinc (Zn), and zirconium (Zr). In addition to the elements, there are columns identifying the form of the simulant used for the analysis, the preparation method and type of crucible (if a crucible was used) employed to dissolve the sample and the type of sample involved. There were three different preparation/crucible combinations investigated for the simulant on a dried-solids basis and on a vitrified-solids basis. Table 2-1 provides a listing of these combinations.

**Table 2-1 A Listing of Preparation Methods Utilized  
with Form of the AY-102/C-106 Melter Feed Slurry Simulant**

<b>Form of Simulant</b>	<b>Preparation Method/Type of Crucible</b>
AY-102/C-106 MFDS (melter feed dried-solids)	Cesium Carbonate Fusion/Pt
AY-102/C-106 MFDS (melter feed dried-solids)	Sodium Peroxide Fusion/Ni
AY-102/C-106 MFS (melter feed dried-solids)	Acidification w HNO <sub>3</sub> /HCl
AY-102/C-106 MFVG (melter feed vitrified-solids)	Cesium Carbonate Fusion/Pt
AY-102/C-106 MFVG (melter feed vitrified-solids)	Potassium Carbonate/Pt
AY-102/C-106 MFVG (melter feed vitrified-solids)	Sodium Peroxide Fusion/Ni

The types of samples for this study included: blanks, trial samples (samples of the simulant), laboratory control samples (LCS), and spiked samples (samples of the simulant spiked with known amounts of one or more elements). The first three types of samples are the focus in the analyses that follow and these are used to provide insight into the relative performances of the dissolution methods investigated as part of this Phase I effort. However, note that the trial samples are the primary focus of the statistical comparisons. Measurements that were below the detection limit of the analytical process (indicated by a “<” in Tables A1 and A2) were replaced by half of the detection limit in the analyses that follow. Also, note that some values were not reported for some elements as indicated by a missing value (a blank) or the letters “NA” (for Not Available) in the tables. An example of this situation is provided by the lack of Ni measurements for samples dissolved in a nickel crucible.

## **2.2 Preliminary Plots of Measurement Data**

Exhibit A1 in the Appendix provides a plot of the measurements by type of sample across all of the forms of the simulant and preparation methods by element in the sequence that the data were reported by ADS.

## **2.3 Statistical Comparisons**

Exhibit A2 in the Appendix provides statistical comparisons among the preparation methods and forms of the simulant for each element for each type of sample. The statistical comparisons include a one-way analysis of variance (ANOVA) for these data (when enough data are available) investigating for a difference in the mean recoveries over these sets of measurements for the specified element. A statistically significant difference in the mean recoveries (at the 5% significance level) is indicated by a

value of 0.05 or less for “Prob>F” in these exhibits. If no value is provided for “Prob>F” in the exhibit, there was not enough data to conduct the statistical test. The means and standard deviations of the sets of measurements for each form of the simulant for each preparation method are also given in this exhibit.

Table 2-2 provides summary information for the measurements generated using the three preparation methods for the dried-solids form of this melter feed slurry simulant along with the LCS and blank samples. Exhibit A3 in the Appendix provides a more specific set of comparisons among the samples of the dried solids form of this melter feed slurry prepared by these three methods. In this exhibit, JMP’s Tukey-Kramer HSD (honestly significant difference) test is used to investigate for all differences among the mean measurements over the three preparation methods for each element. The results of this test for each element is a symmetric matrix covering the preparation methods used with positive entries in the matrix indicating a pair of preparation methods that yielded mean measurements that are significantly different.

In Table 2-2, if the cesium carbonate fusion preparation yielded measurements for the trial samples in Exhibit A3 in the Appendix that indicated a statistically significant different mean from the means of both of the other preparation methods, that entry is shaded.

Multiple digestion methods were tested because no single digestion method is suitable for all of the elemental analyses needed for WTP process control. Although several combinations of two digestion methods would supply the needed elemental analyses, a tandem dissolution approach of a sodium peroxide fusion in a nickel crucible and a warm-acid method has certain advantages in terms of combining a very aggressive digestion (the sodium peroxide fusion) with a very rapid method (the warm-acid method). The former method provides analyses for all elements of interest except Na and Ni while the later method, which may not completely dissolve the sample, does dissolve the Na and Ni elements to provide analyses for this pair of elements that cannot be obtained from the sodium peroxide fusion. This tandem approach was then compared with a cesium carbonate fusion in platinum crucibles. This later approach was investigated because of its potential as a single-digestion method for the elemental analysis of the WTP process samples.

The results from Table 2-2 indicate that the cesium carbonate fusion method yielded measurements with mean values that were statistically smaller at the 5% significance level than the mean values for the measurements from the other two preparation methods for: Fe, Li, Mn, Na, and Pb, while the mean values for Ag, Cu, and Ti for the cesium carbonate fusion method were statistically larger at the 5% significance level than the mean values for the other two preparation methods. The cesium carbonate fusion measurement averages for B, Ba, K, and Zr were statistically different from the means of both of the other preparation methods, even though the cesium carbonate fusion measurement averages fell in between the averages of the measurements of the other two preparation methods. For example, consider Fe, the analyte with the highest measured concentrations for the simulant samples that showed a statistically significant difference among the mean values. The average cesium carbonate fusion value (36,725 µg/g) for Fe is 2.3% smaller than the average sodium peroxide fusion value (37,575 µg/g) and 3.6% smaller than the average warm acid value (38,100 µg/g). However, accuracy and precision requirements for the WTP elemental analyses have not yet been established. Thus, even though there are statistically significant differences, it is not clear that these point to analytical issues at this stage of the study. As seen in the plots of Exhibit A2, the precision was quite good for many of the elements on many of the sets of analyses, which leads to comparisons among the methods that are sensitive to small differences for those elements.

### **3.0 CONCLUSIONS**

The measurement data generated for samples of the RPP-WTP AY-102/C-106 simulant after the addition of glass forming chemicals are presented in this report and the different approaches used to prepare the samples are statistically compared. Comparisons among three of the dissolution methods are highlighted in this analysis. The methods are: sodium peroxide fusion in nickel crucibles, acidification with HNO<sub>3</sub>/HCl at room temperature, and cesium carbonate fusion in zirconium crucibles. A summary table of the measurement averages generated by the three methods is presented. The cesium carbonate fusion method yielded measurements with mean values that were significantly different from the other two preparation methods for several of the elements.
