## ABSTRACT

On July 6, 2004, the Habitat Evaluation Procedure (HEP) was used to determine baseline habitat suitability on the Priest River property, an acquisition completed by the Kalispel Tribe of Indians in 2001. Evaluation species and appropriate models include bald eagle, black-capped chickadee, Canada goose, mallard, yellow warbler, and white-tailed deer. Habitat Suitability Index (HSI) values were visually estimated and agreed upon by all HEP team members. The Priest River Project provides a total of 105.41 Habitat Units (HUs) for the species evaluated. Conifer forest habitat provides 26.95 HUs for bald eagle, black-capped chickadee, and white-tailed deer. Grassland habitat provides 23.78 HUs for Canada goose and mallard. Scrub-shrub vegetation provides 54.68 HUs for mallard, yellow warbler, and white-tailed deer.

## INTRODUCTION

The Habitat Evaluation Procedure (HEP) was developed in 1980 by the U. S. Fish and Wildlife Service (USFWS) (USFWS 1980a, USFWS 1980b). HEP is a species-habitat based approach to assess project impacts, and it is a convenient tool to document the predicted effects of proposed management actions. The Northwest Power Planning Council (NPPC), now known as the Northwest Power and Conservation Council (NPCC), endorsed the use of HEP in its Columbia River Basin Fish and Wildlife Program to evaluate wildlife benefits and impacts associated with the development and operation of the federal Columbia River Basin hydroelectric system (NPPC 1994). The Albeni Falls Interagency Work Group (Work Group) used HEP in 1987 to evaluate wildlife impacts attributed to the Albeni Falls hydroelectric facility (Martin *et al.* 1988).

In 1995-1996, the Work Group (Kalispel Tribe, Coeur d'Alene Tribe, Kootenai Tribe of Idaho, Idaho Department of Fish and Game, USFWS, and U. S. Army Corps of Engineers) began implementing activities to mitigate wildlife habitat losses. Implementation activities include the protection, restoration, and enhancement of wildlife habitat. In 2001, the Kalispel Tribe purchased the Priest River property located north of Priest River, Idaho (Figures 1 and 2). The initial baseline habitat assessment was completed in July 2004. The baseline assessment describes existing ecological conditions on the property and will be used to guide future enhancement activities.

The objective of using HEP at the Priest River Project and other protected properties is to document the quality and quantity of available habitat for selected wildlife species. In this way, HEP provides information on the relative value of the same area at future points in time so that the effect of management activities on wildlife habitat can be quantified. When combined with other tools, the baseline HEP will be used to determine the most effective on-site management, restoration, and enhancement actions to increase habitat suitability for targeted species. The same process will be replicated every five years to quantitatively evaluate the effectiveness of management strategies in improving and maintaining habitat conditions while providing additional crediting to BPA for enhanced habitat values.

Figure 1. Priest River Project vicinity near Priest River, Idaho.

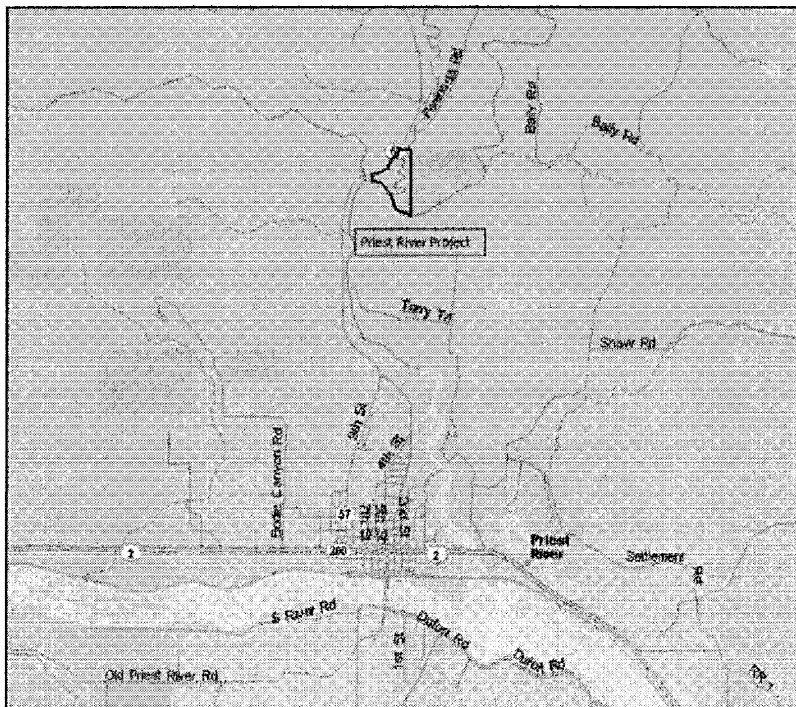

Figure 2. Priest River Project location.

## METHODS

The HEP is based on the assumption that habitat for selected wildlife species can be described by a Habitat Suitability Index (HSI). This value is derived from an evaluation of the ability of key habitat components to supply the life requisites of selected wildlife species. Habitat quality, expressed as an index or HSI, measures how suitable the habitat is for a particular species when compared to optimum habitat. The HSI varies from zero to one (optimum). The value of an area to a given species of wildlife is a product of the size of the area and the quality of the area (HSI) for the species. This product is comparable to "habitat value" and is expressed as a Habitat Unit (HU). One HU is equal to a unit of area (one acre, for example) which has optimum value to the target species.

The HEP team randomly selected various sites within each cover type from which life requisite data were collected. Habitat quality was visually inspected by the HEP team and all values were recorded in the field (Table 1).

**Table 1. Target species, life requisites, and HSI values for the Priest River Project.**

Target Species	Life Requisite	HSI Equation	HSI Value
Bald eagle (breeding)	Reproduction	$(V_2 \times V_3 \times V_4)^{1/3}$	HSI value
Bald eagle (wintering)	Food	$[(V_1)^2 \times V_2]^{1/3}$	HSI value
Black-capped chickadee	Food	$(V_1 \times V_2)^{1/2}$	Lowest value
	Reproduction	$V_3$	
Canada goose	Reproduction	$[(V_1 + V_2) V_3]^{1/2}$	HSI value
Mallard	Reproduction	$V_1$ or $V_2$ or $V_3$	Lowest value
White-tailed deer	Food	$V_1$	HSI value
Yellow warbler	Reproduction	$(V_1 \times V_2 \times V_3)^{1/2}$	HSI value

The bald eagle, black-capped chickadee, Canada goose, and mallard HSI values were determined from one site. Yellow warbler habitat suitability was ascertained from 2 sites, and white-tailed deer habitat values were derived from 3 locations. HSI values were determined using the equations specified in the species models for bald eagle, black-capped chickadee, Canada goose, mallard, yellow warbler, and white-tailed deer<sup>1</sup> (Appendix A). A total of 4 sampling sites were permanently located using a Garmin III global positioning system (Figure 3).

<sup>1</sup> To maintain consistency within the Albeni Falls Wildlife Mitigation Program, modified species models and histograms used by the Kalispel Tribe (Merker 1993) were used at the Priest River Project.

## Priest River - 63 Acres

**Figure 3. HEP sampling locations and habitat cover types on the Priest River Project.**

Habitat cover types were delineated using 1:24,000 scale 1992 U.S. Forest Service aerial photography and on-site verification (Table 2). Supplemental information was used from the USFWS National Wetland Inventory map. Cover type acreage was determined using Arcview 3.1 software (Table 3). The Habitat Units were calculated using the formula:

$$HU = (\text{cover type area}) (\text{HSI value})$$

**Table 2. Priest River Project target species and associated cover types.**

Target Species	Grassland	Scrub-Shrub	Conifer Forest
Bald eagle			X
Black-capped chickadee			X
Canada goose	X		
Mallard	X	X	
Yellow warbler		X	
White-tailed deer		X	X

**Table 3. Cover type acreage for the Priest River Project.**

Cover Type	Acres
Grassland	25.03
Scrub-shrub	27.20
Conifer forest	7.79
<b>Total</b>	<b>60.02</b>

The HEP team collected habitat data along a transect (100-foot intervals) within each cover type. Sampling transects were lengthened to achieve a 90 percent confidence level for parameter point estimates. Adequacy of habitat sampling was determined using the formula (Lapin 1980):

$$\frac{\alpha^2 \times \sigma^2}{e^2}$$

Where:

$\alpha$  = critical normal value ( $p=0.1$ ) from any standard statistical reference

$\sigma$  = standard deviation

$e$  = tolerable error level

Shrub presence, species, and height data were collected at 2-foot intervals along the sampling transect. Percent herbaceous cover and percent herbaceous cover composed of grass were measured using a 0.5 by 1.0 meter sampling frame (Daubenmire 1959) at 50-foot intervals along the transect. Height of the herbaceous layer was measured at 5 points within the sampling frame. A Robel pole (Robel et al. 1970) was used to determine the height-density of the herbaceous layer. Visual obstruction rating (VOR) was determined by four Robel pole measurements, two parallel and two perpendicular to the transect, and taken at 50-foot intervals along the transect. Distances to water, size of water bodies, ratios of open water to emergent vegetation, and road densities were derived from a combination of field estimation and evaluation of aerial photographs and topographic maps.

To determine the suitability of mallard brood-rearing habitat adjacent to the shoreline, aerial photography was examined and field verification was conducted 100 meters from the water's edge. Measurements were taken in the grassland habitat and as the scrub-shrub habitat was deemed similar in cover we applied the same variable scores to the scrub-shrub habitat cover type. These results were applied to the scrub-shrub habitat acreage to determine HUs for that cover type.

## RESULTS

The Priest River Project is comprised of three habitat types. Grassland habitat (25.03 acres) provides 23.78 HUs for Canada goose and mallard. An estimated 27.20 acres contain scrub-shrub vegetation, providing a total of 54.68 HUs for mallard, yellow warbler, and white-tailed deer. The conifer forest habitat type (7.79 acres) provides 26.95 HUs for bald eagle, black-capped chickadee, and white-tailed deer. Table 4 summarizes the HEP results for the Priest River

Project. A total of 105.41 baseline habitat units (1.76 HUs/acre) have been protected by the purchase of this property.

**Table 4. HEP results for the Priest River Project.**

Cover Type/ Target Species	HEP Variable	Var. Score	HSI Equation	HSI Score	Acres	HUs
<b>Conifer Forest</b>						
Bald eagle (wintering)	V <sub>1</sub> - Food	1.00	$[(V_1)^2 * V_2]^{1/3}$	0.97	7.79	7.55
	V <sub>2</sub> - Perch	0.90

<b>Total</b>					<b>60.02</b>	<b>105.41</b>

## DISCUSSION

### *Grassland*

The grassland habitat type (25.03 acres) provides a total of 23.78 HUs for Canada goose and mallard. Habitat suitability for Canada goose is below moderate and is limited by the lack of nearby islands ( $V_1$ ), and grass that is too tall and dense for brood-rearing and foraging ( $V_2$ ). The grassland habitat type provides 11.26 HUs for Canada goose. An estimated 12.52 HUs of moderate habitat quality are provided for mallard. Mallard habitat suitability is limited by the lack of seasonally flooded wetlands ( $V_1$ ) as well as the height and density of nesting cover ( $V_2$ ) available.

### *Scrub-Shrub*

Scrub-shrub vegetation consists of 27.20 acres and provides 54.68 HUs for mallard, yellow warbler, and white-tailed deer. The scrub-shrub cover type provides 20.00 HUs for yellow warbler, the habitat suitability for which is limited by below moderate deciduous shrub density ( $V_1$ ). Scrub-shrub habitat provides 21.08 HUs for white-tailed deer and 13.60 HUs for mallards.

### *Conifer Forest*

Nearly 13% of the Priest River Project is comprised of conifer forest (7.79 acres). This habitat type provides 29.35% of the total baseline HUs available on the Project. Conifer forest provides near optimal habitat and 13.32 HUs for wintering and breeding bald eagle. Black-capped chickadee habitat is optimal as is indicated by an HSI score of 1.00. Currently, the coniferous forested habitat provides 7.79 HUs for black-capped chickadee. White-tailed deer habitat suitability is limited by the lack of palatable hydrophytic shrubs such as willow (*Salix spp.*), red-osier dogwood (*Cornus stolonifera*), and alder (*Alnus rubra*). A total of 5.84 baseline HUs are provided for white-tailed deer.

## ACKNOWLEDGMENTS

We would like to extend our thanks to Paul Ashley and his HEP team for providing their data collection assistance and insightful ideas about enhancement potentials. We would also like to thank Stacey Stovall for her assistance in the completion of this report.

**APPENDIX A**  
**Habitat Suitability Index Models**

## **Bald Eagle Habitat Suitability Index Model**

### Overview

This model recognizes that proximity to prey base, quality of prey base, quality of nesting and perching habitat, and amount of human disturbance are the most important components determining the quality of breeding and wintering bald eagle habitat.

This HSI model was taken from:

Martin, R. C., H. J. Hansen, and G. A. Meuleman. 1988. Albeni Falls wildlife protection, mitigation and enhancement plan. Project no. 87-43. Bonneville Power Administration. 123 pp.

**V<sub>1</sub>** Breeding and wintering food requirements

Good. Abundant prey base (ungulate carrion, fish of several species, waterfowl, small mammals) available throughout the year within three miles of potential nest/perch site.

SI value = 1.0.

Moderate. Moderate prey availability within three miles of potential nest/perch site. Water sometimes frozen over early in the nesting/perching period, but some ungulate carrion available during that time. Alternative food sources may be within five miles of nest or perch.

SI value = 0.8.

Fair. Minimal prey base within five miles of potential nest/perch site. Water frozen over late into the nesting cycle without alternative food sources.

SI value = 0.3.

Poor. Insufficient prey base to sustain eagles.

SI value = 0.0.

---

**V<sub>2</sub>** Nest/perch structure: type, form, density

Best. Old growth spruce, Douglas fir, or ponderosa pine in coniferous areas; old growth cottonwood in deciduous stands; stands dense and continuous and exceeding 10 acres in size.

SI value = 1.0.

Good. Scattered old growth trees in stands of moderate (mature) aged trees

(cottonwoods, spruce, fir, ponderosa pine) exceeding 10 acres in size.

SI value = 0.9.

Fair. Scattered old growth trees (cottonwoods, spruce, fir, ponderosa pine) in open areas (without screening from younger aged trees).

SI value = 0.6

Poor. Dominant trees available are old growth lodgepole pine in coniferous areas or aspen in deciduous stands.

SI value = 0.4.

Minimal. Potential nest or perch structures are shrubs or young trees, no screening present.

SI value = 0.0.

---

**V<sub>3</sub>** Distance to water body with sufficient prey availability

A.  $\leq 1$  kilometer. SI value = 1.0.

B. 2 kilometers. SI value = 0.9.

C. 3 kilometers. SI value = 0.6.

D. 4 kilometers. SI value = 0.2.

E.  $\geq 4.5$  kilometers. SI value = 0.0.

**V<sub>4</sub>** Human activity level

Good. Natural vegetation dominates area; no permanent developments or human structures; no human activity within the area during the nesting period.

SI value = 1.0.

Moderate. Area of farming ground or pasture surrounds site; occasional use of area by predictable humans, such as a farmer or stockman; human activity occurs late in the eagle nesting cycle.

SI value = 0.9.

Fair. Dispersed recreation campsites or trails, or occasionally used boat docks within vicinity of potential nest or perch; activity occurs during brooding period only.

SI value = 0.4.

Poor. Developed sites, e.g. campgrounds, boat launches, etc., within vicinity of potential nest or perch; heavy human use of area during incubation period.

SI value = 0.0.

**Equation**

Winter food suitability index value =  $V_1$

Winter perch suitability index value =  $V_2$

Wintering bald eagle habitat suitability index value =  $[(V_1)^2 \times V_2]^{1/3}$

Reproductive suitability index value =  $(V_2 \times V_3 \times V_4)^{1/3}$

Breeding bald eagle habitat suitability index value is the lower of food or reproductive suitability index values.

## **Black-capped Chickadee Habitat Suitability Index Model**

### Overview

This model considers the ability of the habitat to meet the food and reproductive needs of the black-capped chickadee as an indication of the overall habitat suitability. Cover needs are assumed to be met by the food and reproductive requisites and water is assumed not to be limiting. The food component assesses vegetation conditions, and the reproduction component assesses the abundance of suitable snags.

This HSI model was modified into a histogram from:

Schroeder R. L., 1983. Habitat suitability index models: black-capped chickadee. U. S. Dept. Int., Fish Wildl. Serv. FWS/OBS-82/10.37. 21 pp.

**V<sub>1</sub>** Percent tree canopy closure

Percent tree canopy closure is the percent of canopy closed by vertical projection of the canopy in the cover type.

**V<sub>2</sub>** Average height of overstory trees

The average height of overstory trees is the average height from the ground of the overstory trees present in the cover type.

**V<sub>3</sub>** Number of snags 10 – 25 cm/0.4 ha.

Number of snags 10 – 25 cm/0.4 ha. is the number of snags usable by black-capped chickadees in the cover type.

#### Equation

<u>Life Requisite</u>	<u>Cover Type</u>	<u>Equation</u>
Food	DF, DFW	$(V_1 \times V_2)^{1/2}$
Reproduction	DF, DFW	$V_3$

The Habitat Suitability Index value is equal to the lowest life requisite value.

## **Canada Goose Habitat Suitability Index Model**

### Overview

This model recognizes that the quality of shoreline habitat, the presence of islands, and the quality of brood-rearing habitat are the most important components determining the quality of Canada goose breeding habitat.

This model was taken from:

Martin, R. C., H. J. Hansen, and G. A. Meuleman. 1988. Albeni Falls wildlife protection, mitigation and enhancement plan. Project no. 87-43. Bonneville Power Administration. 123 pp.

**V<sub>1</sub>** Island nesting habitat

Good. Stable islands present, relatively high shoreline/area ratio; ground cover on portions of islands 4 to 16 inches high; brood habitat within 1 mile of area.

SI value between 0.8 and 1.0.

Fair. Stable islands present; relatively low shoreline/area ratio; or cover on islands < 4 or > 16 inches in height or brood habitat within 1 to 2 miles from area.

SI value between 0.5 and 0.7.

Poor. No stable islands present; or islands with limited or no cover; or brood habitat  $\geq 2$  miles from area.

SI value between 0.0 and 0.4.

---

**V<sub>2</sub>** Shoreline nesting habitat

Good. Portions of cover within 10 meters of water; ground cover 4 to 16 inches high; adjacent wetland buffer within 50 meters of shoreline, may include sloughs of open water; brood habitat within 1 mile.

SI value = 0.5.

Fair. Portions of shoreline cover within 10 meters of water; ground cover 4 to 16 inches high; adjacent wetland buffer within 50 meters of shoreline (Does not include open water wetlands); or brood habitat 1 to 2 miles away.

SI value between 0.3 and 0.4.

Poor. No shoreline cover or shoreline cover taller than 16 inches and/or shorter than 4 inches; or wetland buffer > 50

meters to absent or brood habitat > 2 miles away.

SI value between 0.0 and 0.2.

---

**V<sub>3</sub>** Brood rearing habitat

Good. Brood pasture easily accessible from main water body; foraging zones common; vegetation < 4 inches tall; average > 1 acre in size; open water wetlands are present within 1 mile of nesting habitat.

SI value between 0.7 and 1.0.

Fair. Less than above and/or no open water wetlands; or area is 1 to 2 mile miles from nesting habitat.

SI value between 0.4 and 0.6.

Poor. Little or no brooding area; or area is  $\geq 2$  miles from nesting habitat.

SI value between 0.0 and 0.3.

---

**Equation**

The Habitat Suitability Index value =  $[(V_1 + V_2) V_3]^{1/2}$

**Mallard Habitat Suitability Index Model  
(Breeding Season Only)**

Life Requisite Values

Food ( $V_1$ ): Related to the area of various wetland types within a sampling area that are shallow enough for a dabbling duck to feed (<60 cm water depth is optimum) during the breeding season. Model assumes that seasonally flooded wetlands (i.e. wet meadows, etc.) provide a better food source than permanently flooded wetlands.

Reproduction ( $V_2$ ): Related to the height and density of nesting cover (residual vegetation).

Cover ( $V_3$ ): Related to the percent of shoreline dominated by emergent or scrub-shrub wetland vegetation. Shorelines with little or no vegetation provide marginal escape cover for broods. Only wetlands with open water available during the brooding season should be evaluated.

Habitat Evaluation Criteria

Food ( $V_1$ ): Seasonal wetlands, which produce the highest quantities of aquatic invertebrates, are preferred feeding habitat for laying mallard hens. The density of mallard pairs/hectare is assumed to be higher in seasonal rather than semi-permanent wetlands.

A – Temporarily Flooded: Surface water is present for brief periods during growing season.

SI value = 0.3

B – Seasonally Flooded: Surface water is present for extended periods especially early in the growing season, but is absent by the end of the season in most years.

SI value = 1.0

C – Semi-permanently Flooded: Surface water persists throughout the growing season during most years.

SI value = 0.8

D – Permanently Flooded: Water covers the land surface throughout the year in all years. Vegetation is composed of obligate hydrophytes.

SI value = 0.5

Reproduction ( $V_2$ ): Mallard nesting success is the highest in cover with the greatest height-density of residual vegetation (i.e. concealed from all directions). The Robel method was used as the visual obstruction technique (height and density). Reproduction value ( $V_2$ ) is a function of the height and density of nesting cover (residual vegetation).

Shoreline Cover ( $V_3$ ): Mallard broods will utilize wetlands having sparse to dense emergent or scrub-shrub vegetation. Wetlands devoid of wetland vegetation or open water are usually avoided. Marshes with shorelines bare of emergent vegetation are used less. Measure the percent of shoreline dominated by emergent and/or scrub-shrub wetland vegetation for brood rearing wetlands (>2 acres in size with some open water during brooding season):

A – 50% to 100% of shoreline	SI value = 0.7 to 1.0
B – 15% to 50% of shoreline	SI value = 0.4 to 0.6
C – 0% to 15% of shoreline	SI value = 0.1 to 0.3

The habitat suitability index is the lowest  $V_n$  value.

#### Suggested Measurement Techniques

Large sampling areas that are representative should be randomly selected. At least four sampling areas per area should be used. Variables  $V_1$  and  $V_3$  can be measured from aerial photography with field ground truthing. Variable  $V_2$  should be measured in the field in upland habitat adjacent to wetlands. Specific suggestions on measurement techniques of each variable are provided below.

- $V_1$  = Calculate area of various wetland types within each sampling area using a digitizer or dot grid or planimeter. Multiply each wetland area by its SI for a weighted value. Sum the weighted values in the sampling area and divide by the total wetland acreage for a weighted sample area SI value.
- $V_2$  = Field measure height and density of residual vegetation using the visual obstruction technique (Robel pole used here). Sampling areas should be located on aerial photographs.
- $V_3$  = Measure the amount of shoreline vegetation for each wetland type >2 acres in size and with some open water during brood-rearing season from aerial photographs. Calculate SI value for each wetland based on measurements. Multiple SI value times wetland area for a weighted value. A standard for lacustrine systems (i.e. littoral zone or 100 meters from shore) will need to be established as providing brood-rearing habitat. Sum weighted values in each sampling area and divide by total wetland acreage for a sample area SI value. Some field verification of shoreline vegetation should be conducted.

## **Muskrat Habitat Suitability Index Model**

### Overview

Year-round habitat requirements of the muskrat can be fulfilled within wetland habitats that provide herbaceous vegetation and permanent surface water with minor fluctuations in water levels. Wetlands characterized by seasonal drying, an absence of emergent vegetation, or both, have less potential as year-round muskrat habitat than wetlands with permanent water and an abundance of emergent vegetation. It is assumed that food and cover are interdependent characteristics of the muskrat's habitat and that measures of vegetative abundance and water permanence within a wetland can be aggregated to reflect habitat conditions favoring maintenance of the muskrat's food and cover requirements. The reproductive habitat requirements of the species are assumed to be met when adequate water, food, and cover conditions are present.

This model was modified into a histogram from:

Allen, A. W., and R. D. Hoffman. 1984. Habitat suitability index models: Muskrat. U.S. Fish Wildl. Serv. FWS/OBS-82/10.46. 27 pp.

**V<sub>1</sub>** Percent canopy cover of emergent herbaceous vegetation

Percent canopy cover of emergent herbaceous vegetation is the percent of the water surface shaded by a vertical projection of the canopies of all emergent herbaceous vegetation, both persistent and non-persistent.

**V<sub>8</sub>** Percent of emergent herbaceous vegetation of preferred types

Percent of emergent herbaceous vegetation consisting of Olney bulrush, common threesquare bulrush, or cattail considering both persistent and non-persistent types.

#### Equation

Life Requisite	Cover Type	Equation
Cover	HW	$(V_1 \times V_2)^{1/2}$
Food	HW	$(V_1 \times V_8)^{1/2}$

The Habitat Suitability Index value is equal to the lowest life requisite value.

**V<sub>2</sub>** Percent of year with surface water present

Percent of year with surface water present is the proportion of the year in which the cover type has surface water present.

## **Yellow Warbler Habitat Suitability Index Model**

### Overview

It is assumed that optimal habitats contain 100% hydrophytic deciduous shrubs and that habitats with no hydrophytic shrubs will provide marginal suitability. Shrub densities between 60 and 80% crown cover are assumed to be optimal. As shrub densities approach zero cover suitability also approaches zero. Totally closed shrub canopies are assumed to be of only moderate suitability, due to the probable restrictions on movement of the warblers in those conditions. Shrub heights of 2 m or greater are assumed to be optimal, and suitability will decrease as the heights decrease.

This model was modified into a histogram from:

Schroeder, R. L. 1982. Habitat suitability index models: yellow warbler. U.S. Dept. Int., Fish Wildl. Serv. FWS/OBS-82/10.27. 7 pp.

**V<sub>1</sub>** Percent deciduous shrub crown cover

Percent deciduous shrub crown cover is the percent of the ground shaded by the vertical projection of the canopies of woody deciduous vegetation that is less

**V<sub>3</sub>** Percent of deciduous shrub canopy comprised of hydrophytic shrubs

Percent of deciduous shrub canopy comprised of hydrophytic shrubs is the relative percent of the amount of hydrophytic shrubs as compared to all shrubs based on V<sub>2</sub>.

than 5 m in height.

**V<sub>2</sub>** Average height of deciduous shrub canopy

Average height of deciduous shrub canopy is the average height from the ground to the top of those shrubs which comprise the uppermost shrub canopy.

### Equation

The Habitat Suitability Index value =  $(V_1 \times V_2 \times V_3)^{1/2}$

---

**White-tailed Deer Habitat Suitability Index Model  
(Winter Only)**

Overview

This Suitability Index curve recognizes that the most important components determining the quality of white-tailed deer winter habitat are available browse, snow depth, and security cover. It is assumed that snow depth and cover do not limit white-tailed deer in the area surrounding Lake Pend Oreille, compared to the importance of available browse. Therefore, this Suitability Index alone is used to determine white-tailed deer winter habitat quality in the area around Albeni Falls Dam.

**V<sub>4</sub>** Percent shrub crown cover < 1.5 m (5 ft.) in height
