The structures of two facially coordinated Group VII metal complexes are reported, namely: *fac*-bromido[2-(2,2'-bipyridin-6-yl)benzoic acid- κ^2N,N']tricarbonylmanganese(I) tetrahydrofuran monosolvate, $[\text{MnBr}(\text{C}_{17}\text{H}_{12}\text{N}_2\text{O}_2)(\text{CO})_3]\cdot\text{C}_4\text{H}_8\text{O}$, **I**, and *fac*-[2-(2,2'-bipyridin-6-yl)benzoic acid- κ^2N,N']tricarbonylchloridorhenium(I) tetrahydrofuran monosolvate, $[\text{ReCl}(\text{C}_{17}\text{H}_{12}\text{N}_2\text{O}_2)(\text{CO})_3]\cdot\text{C}_4\text{H}_8\text{O}$, **II**. In both complexes, the metal ion is coordinated by three carbonyl ligands, a halide ion, and a 2-(2,2'-bipyridin-6-yl)benzoic acid ligand, in a distorted octahedral geometry. In manganese complex **I**, the tetrahydrofuran (THF) solvent molecule could not be refined due to disorder. The benzoic acid fragment is also disordered over two positions, such that the carboxylic acid group is either positioned near to the bromide ligand or to the axial carbonyl ligand. In the crystal of **I**, the complex molecules are linked by a pair of C—H \cdots Br hydrogen bonds, forming inversion dimers that stack up the *a*-axis direction. In the rhenium complex **II**, there is hydrogen bonding between the benzoic acid moiety and a disordered co-crystallized THF molecule. In the crystal, the molecules are linked by C—H \cdots Cl hydrogen bonds, forming layers parallel to (100) separated by layers of THF solvent molecules.

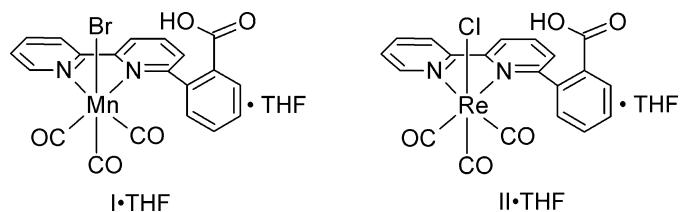

1. Chemical context

Crystal structures of *fac*-[$M(2,2'\text{-bipyridyl})(\text{CO})_3X]^{n+}$ ($M = \text{Mn}^{\text{I}}$ or Re^{I} , $X = \text{monoanionic ligand}$, $n = 0$ or $X = \text{neutral ligand}$, $n = 1$) complexes have been reported for complexes bearing many different bipyridyl derivatives. Among the numerous examples are structures reported by Chen *et al.* (2005), Gerlits & Coppens (2001), and Horn *et al.* (1987). Complexes of the type *fac*-[$\text{Re}(2,2'\text{-bipyridyl})(\text{CO})_3X]^{n+}$ and *fac*-[$\text{Mn}(2,2'\text{-bipyridyl})(\text{CO})_3X]^{n+}$, are of particular interest as selective catalysts for the reduction of CO_2 to CO (Bourrez *et al.*, 2011; Hawecker *et al.*, 1986; Smieja *et al.*, 2013; Sampson *et al.*, 2014; Machan *et al.*, 2014; Smieja & Kubiak, 2010). The addition of weak Brønsted acids such as water or methanol are necessary for the catalytic turnover of Mn complexes (Smieja *et al.*, 2013) and they also significantly increase the catalytic rate of Re complexes (Smieja *et al.*, 2012). Moreover, the use of bipyridyl ligands in these complexes containing phenolic functional groups positioned near the CO_2 binding site, which can act as intramolecular proton donors, have been shown to enhance catalytic performance. *fac*-Tricarbonylbromido-[2-(2,2'-bipyridin-6-yl)- κ^2N,N']phenol)manganese(I) showed enhanced catalytic activity for the reduction of CO_2 to CO

OPEN ACCESS

compared to *fac*-tricarbonylbromido(2,2'-bipyridine)-manganese(I) (Agarwal *et al.*, 2015). *fac*-Tricarbonylbromido-[2-(4-phenyl-2,2'-bipyridin-6-yl- κ^2N,N')benzene-1,3-diol]-manganese(I) was found to electrocatalytically reduce CO₂ to a mixture of CO and formic acid in the absence of external Brønsted acids (Franco *et al.*, 2014). In the presence of external Brønsted acids, selectivity for formate *versus* CO was found to depend on acid strength (Franco *et al.*, 2017).

Herein, we report on the syntheses and structural characterizations of two new complexes of the type *fac*-[$M(2,2'\text{-bipyridyl})(\text{CO})_3X]^{n+}$, *viz.* *fac*-bromido[2-(2,2'-bipyridin-6-yl)benzoic acid- κ^2N,N']tricarbonylmanganese(I) tetrahydrofuran monosolvate, **I**, and *fac*-[2-(2,2'-bipyridin-6-yl)benzoic acid- κ^2N,N']tricarbonylchlororhenium(I) tetrahydrofuran monosolvate, **II**, in which the bipyridyl ligand contains a different type of intramolecular proton donor positioned near the CO₂ binding site. These complexes are the first reported examples of a bipyridyl ligand containing a 2-(2,2'-bipyridin-6-yl)benzoic acid backbone in which the benzoic acid moiety remains protonated and does not coordinate to the metal.

2. Structural commentary

The molecular structures of compounds **I** and **II** are illustrated in Figs. 1 and 2, respectively. Both compounds crystallize as tetrahydrofuran (THF) monosolvates, THF having been used for the recrystallization of both compounds. The metal atoms exhibit distorted octahedral geometries and contain primary

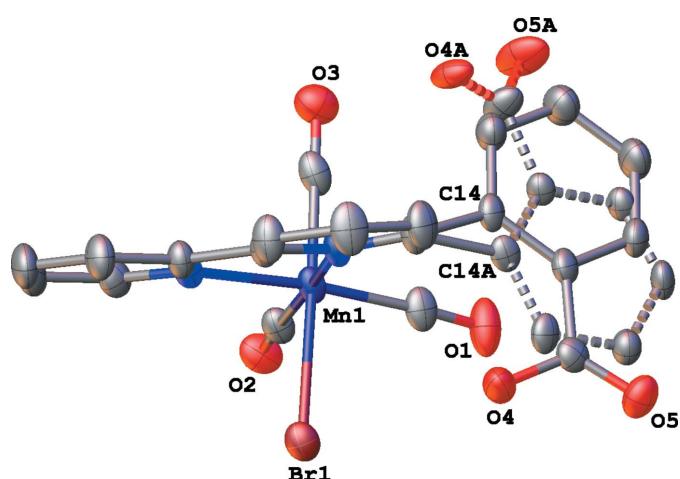

Figure 1

The molecular structure of compound **I**, with partial atom labeling and 50% probability displacement ellipsoids. Both disorder components of the benzoic acid group are shown (the minor one with dashed lines), and H atoms have been omitted for clarity.

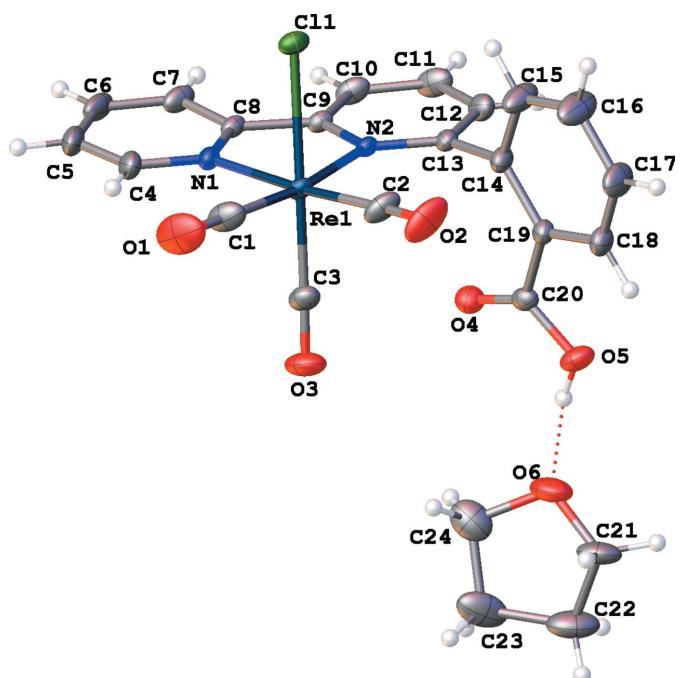

Figure 2

A molecular structure of compound **II**, with atom labeling and 50% probability ellipsoids. The two minor solvent disorder components have been omitted for clarity

coordination spheres similar to those of other *fac*-[Re(α -diimine)(CO)₃Cl] and *fac*-[Mn(α -diimine)(CO)₃Br] complexes; including *fac*-tricarbonylchlorido(4,4'-dihydroxy-2,2'-bipyridine)rhenium(I) (**III**; Manbeck *et al.*, 2015), *fac*-tricarbonyliodo(2,2'-bipyridine)manganese(I) (**IV**; Stor *et al.*, 1995), and *fac*-tricarbonylbromido[2-(2,2'-bipyridin-6-yl- κ^2N,N')-phenol]manganese(I) (**V**; Agarwal *et al.*, 2015). The metal-ligand bond distances are similar to those previously reported for complexes of this type, for *e.g.*, in **I** the Mn–N bond

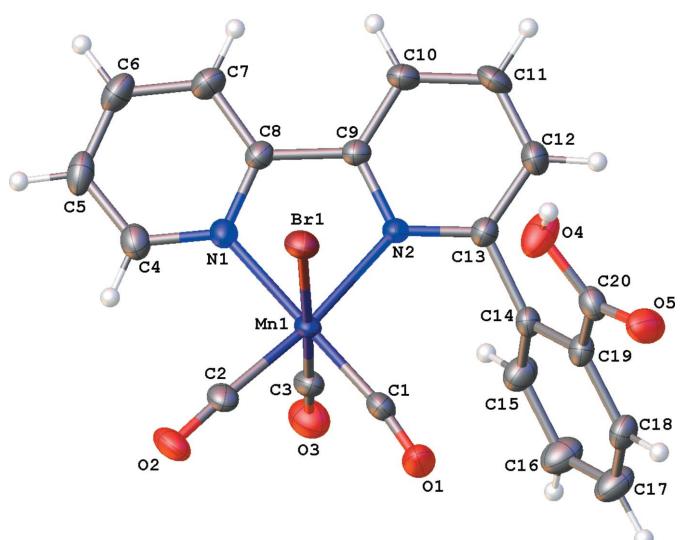

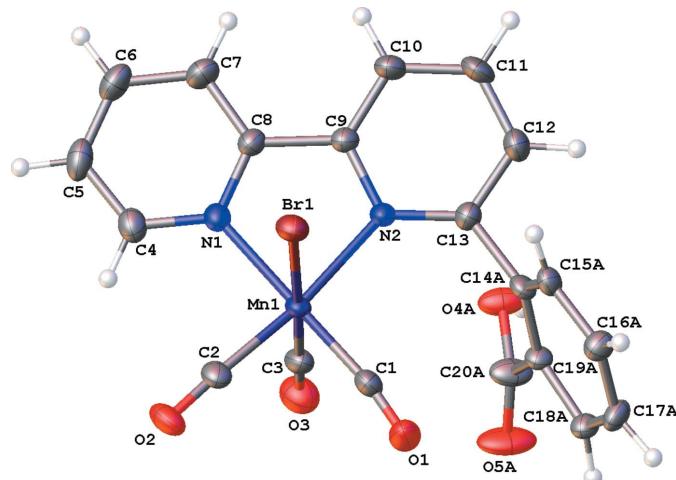

Figure 3

distances are 2.029 (2) and 2.082 (2) Å, while in **V** the Mn—N bond distances are 2.0347 (8) and 2.091 (1) Å.

In **I**, the benzoic acid fragment is disordered over two positions (Fig. 1). In the major component, the carboxylic acid group is positioned near the bromide ligand (see Fig. 3), whereas in the minor component the benzoic acid fragment is rotated such that the carboxylic acid group is positioned near the axial carbonyl ligand (see Fig. 4). In **II**, the benzoic acid fragment is not disordered, and the carboxylic acid group is positioned near the axial carbonyl ligand (Fig. 2).

Molecules with similar motifs, in which a benzoic acid is bound to a pyridyl ring in the *ortho* position (Charris-Molina *et al.*, 2017) or to a phenyl ring in the *ortho* position (Dobson & Gerkin, 1998), have been structurally characterized. Compared to the torsion angles between the benzoic acid fragment and the pyridyl or phenyl rings in these structures, the benzoic acid fragment and the pyridyl ring in **I** and **II** are closer to being perpendicular to each other, with the N2—C13—C14—C19 torsion angle being $-116.4 (3)^\circ$ in the major component of **I** and $100.55 (19)^\circ$ in **II**. In the minor component of **I**, the N2—C13—C14A—C19A torsion angle is $85.7 (8)^\circ$. In contrast, for the structures reported by Charris-Molina *et al.* (2017) the analogous torsion angles are $52.6 (4)$, $-40.5 (3)$, $-51.5 (5)$ and $48.8 (3)^\circ$. In the structure of biphenyl-2-carboxylic acid itself (Dobson & Gerkin, 1998), the analogous torsion angles of the four molecules of the asymmetric unit are $-46.7 (4)$, $-52.3 (4)$, $48.2 (4)$ and $52.3 (4)^\circ$. Smaller absolute values of the torsion angles for **I** and **II** would result in closer contacts between the atoms of the benzoic acid fragment and the ancillary ligands around the metal, which may explain the more perpendicular torsion angles found in **I** and **II**.

3. Supramolecular features

In compound **I**, the THF solvate molecule is disordered over several positions and probably forms intermolecular hydrogen

bonds. In the crystal, complex molecules are linked by pairs of C—H···Br hydrogen bonds, forming inversion dimers (Table 1). A view of the crystal packing is given in Fig. 5 and shows the voids occupied by the disordered THF solvent molecules.

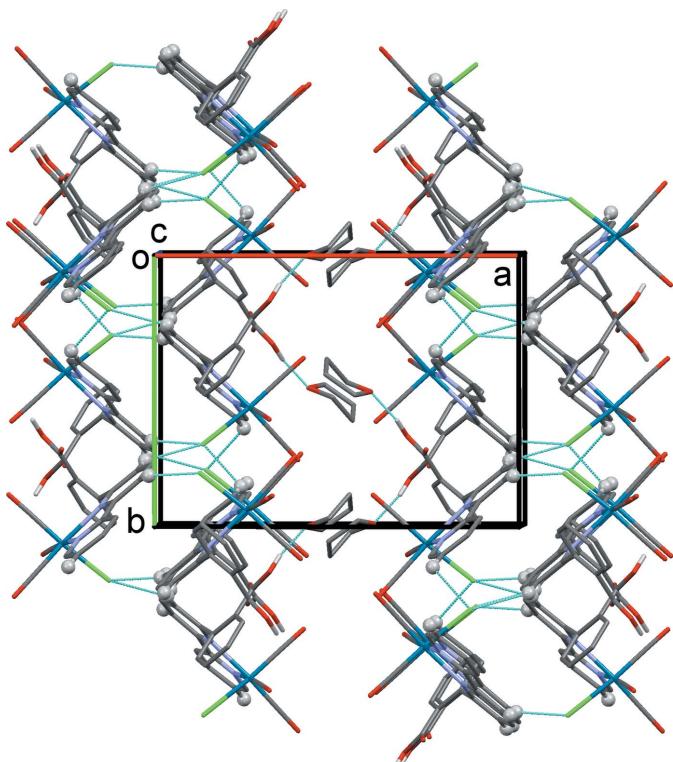

In compound **II**, there is hydrogen bonding between the benzoic acid group and the oxygen atom of the disordered THF molecule (Table 2). In the crystal, the complex molecules are linked by C—H···Cl hydrogen bonds, forming layers lying parallel to the *bc* plane (Table 2 and Fig. 6), which are separated by layers of THF solvent molecules.

4. Database survey

A search of the Cambridge Structural Database (Version 5.39, last update February 2018; Groom *et al.*, 2016) for complexes

**Figure 5**

A view along the *a* axis of the crystal packing of compound **I**. The C—H···Br hydrogen bonds (Table 1) are shown as dashed lines and the regions occupied by the disordered THF solvent molecules as yellow/brown cavities (Mercury; Macrae *et al.*, 2008). Only the major component of the disordered benzoic acid group is shown.

**Figure 6**

A view along the *c* axis of the crystal packing of compound **II**. The O—H···O and C—H···Cl hydrogen bonds are shown as dashed lines (Table 2). Only the major component of the disordered THF molecule is shown and H atoms not involved in these interactions have been omitted for clarity.

containing a polypyridine ligand with an *o*-benzoate substituent in the 6-position of the polypyridine moiety gave two hits, *viz.* [2-(2,2':4',2''-terpyridin-6'- κ^2 *N*¹,*N*'')benzoato- κ O]manganese(II) trihydrate (CSD refcode MEWBAT; Liu, 2013) and {[dimethyl(phenyl)silyl]acetato}-[*N*-(3,5-di-*t*-butylphenyl)-2-{6-[3,5-di-*t*-butyl-2-({[tris(pentafluorophenyl)- λ^5 -boranyl]oxy}carbonyl)phenyl]pyridin-2-yl}quinolin-8-amine]-scandium toluene solvate (RIPLOT; LeBlanc *et al.*, 2014). Unlike in **I** and **II**, the benzoate substituent in these complexes is deprotonated and coordinates to the metal forming a seven-membered chelate ring. The reaction conditions and the low oxidation number of the metals in **I** and **II** would be expected to disfavor deprotonation of the benzoic acid substituent and its coordination to the metal.

5. Electrochemistry

In order to determine whether **I** and **II** could act as precatalysts for the reduction of CO₂, cyclic voltammetry experiments were performed. These studies were conducted in acetonitrile containing 1 mM **I** or **II** and 0.1 M tetrabutylammonium hexafluorophosphate using a glassy carbon working electrode, a platinum wire auxiliary electrode, and an Ag/Ag⁺ non-aqueous reference electrode. Ferrocene was used as an internal standard. In order to determine whether a catalytic current enhancement was observed in the presence of

the substrate, the current response was measured under an inert gas atmosphere, after bubbling CO₂ through the solution, and after bubbling CO₂ through the solution in the presence of an external Brønsted acid (5% water by volume). In the presence of CO₂ and water, similar complexes have shown a catalytic current enhancement at the potential at which the complexes undergo a second one-electron reduction (Bourrez *et al.*, 2011; Agarwal *et al.*, 2015; Smieja & Kubiak, 2010). Interestingly, neither complex presented here showed electrocatalytic activity for the reduction of CO₂ at or near this potential, even in the presence of an external Brønsted acid (5% water by volume). In order to probe whether catalysis was inhibited specifically by the intramolecular nature of the benzoic acid substituent, the cyclic voltammetry of *fac*-[Mn(2,2'-bipyridyl)(CO)₃Br] was performed in the presence of CO₂, 5% water, and up to 50 molar equivalents of benzoic acid. Even in the presence of 50 molar equivalents of benzoic acid, the current enhancement was similar to that in the presence of only CO₂ and 5% water (Bourrez *et al.*, 2011), indicating that it is the presence of the benzoic acid substituent in an intramolecular fashion that inhibits catalysis.

6. Synthesis and crystallization

Toluene, ethanol, and acetonitrile used in syntheses were degassed by sparging with N₂. THF, hexane, and pentane were dried over molecular sieves and degassed using the freeze-pump-thaw method when used for recrystallization. All other reagents and solvents were purchased commercially and used as received. Metallated complexes were manipulated and stored in the dark to minimize exposure to light.

Synthesis of methyl 2-(2,2'-bipyridin-6-yl)benzoate: The reagents 6-bromo-2,2'-bipyridine (0.500 g, 2.13 mmol) and 2-methoxycarbonylphenylboronic acid, pinacol ester (0.715 g, 2.73 mmol) and the catalyst tetrakis(triphenylphosphine)-palladium(0) (0.11 g, 0.095 mmol) were placed in a Kjedahl-shaped Schlenk flask. The flask was then evacuated and refilled with nitrogen three times, ending with the flask under nitrogen. Toluene (26 ml), ethanol (2.6 ml), and 2 M aqueous K₂CO₃ (2.1 ml) were added to the flask, which was then heated at 368 K under nitrogen under stirring for 41 h. The reaction mixture was cooled to room temperature, and then saturated aqueous ammonium chloride (26 ml) and deionized water (26 ml) were added to the reaction flask. The product mixture was then extracted with dichloromethane three times (42 ml, 30 ml, 25 ml). The combined organic layers were dried over magnesium sulfate and then filtered. The solvent was removed under vacuum. The product was purified by column chromatography using silica gel 60 as the solid phase and diethyl ether as the eluant (*R*_f = 0.60). (yield 0.395 g, 63.9%) ¹H NMR (270 MHz, CDCl₃) (ppm): 88.69 (*d*, 1H, *J* = 4.7 Hz), 88.51–8.48 (*m*, 2H), 87.95–7.84 (*m*, 2H), 87.77 (*dd*, 1H, *J* = 7.5 Hz, *J* = 1.3 Hz), 87.69–7.45 (*m*, 4H), 87.34 (poorly resolved multiplet, 1H), 83.53 (*s*, 3H). MS (ES-API): found *m/z* = 291.1 [M + H]⁺; {C₁₈H₁₅N₂O₂⁺} requires 291.1.

Synthesis of 2-(2,2'-bipyridin-6-yl)benzoic acid: Water (7.7 ml) containing 0.77 g (19 mmol) of dissolved sodium

Computer programs: *APEX3* and *SAINT-Plus* (Bruker, 2015), *SHELXT* (Sheldrick, 2015a), *SHELXL* (Sheldrick, 2015b), *OLEX2* (Dolomanov *et al.*, 2009), *Mercury* (Macrae *et al.*, 2008) and *PLATON* (Spek, 2009).

hydroxide was added to methyl 2-(2,2'-bipyridin-6-yl)-benzoate (0.175 g, 0.60 mmol). The reaction mixture was refluxed for 3 h under stirring. The reaction was then cooled to room temperature. Aqueous hydrochloric acid (2 N) was added dropwise until the pH was approximately 4. The white precipitate that appeared was collected on a Büchner funnel by vacuum filtration. The precipitate was washed with 4 ml deionized water and then dried *in vacuo* (yield 0.167 g, 100%). ¹H NMR (270 MHz, D₂O containing 1 M NaOH) (ppm): δ 8.84 (*d*, 1H, *J* = 4.6 Hz), δ 8.46 (*d*, 1H, *J* = 8.1 Hz), δ 8.21–8.29 (*m*, 3H), δ 7.88–9.95 (*m*, 2H), δ 7.71–7.81 (*m*, 4H).

Synthesis of compound I: Bromopentacarbonyl-manganese(I) (0.0525 g, 0.191 mmol) and 2-(2,2'-bipyridin-6-yl)benzoic acid (0.0500 g, 0.181 mmol) were placed in a Schlenk flask, which was then evacuated and refilled with nitrogen three times, ending with the flask under nitrogen. Acetonitrile (9.4 ml) was added to the flask, which was then covered with aluminium foil. The reaction was heated to 333 K and stirred under a nitrogen atmosphere for 12 h. The reaction was cooled to room temperature and the solvent then removed under vacuum. The crude product was dissolved in a minimal amount of THF and recrystallized by slow diffusion of hexane into the solution. These recrystallization conditions performed on a smaller scale produced the yellow needle-like crystals used for X-ray crystallographic analysis. IR ν_{CO} (KBr pellet, cm⁻¹): 2019(*s*), 1933(*s*), 1912(*s*).

Synthesis of compound II: Pentacarbonylchlororhenium(I) (0.0273 g, 0.0755 mmol) and 2-(2,2'-bipyridin-6-yl)benzoic acid (0.0207 g, 0.0749 mmol) were placed in a Schlenk flask, which was then evacuated and refilled with nitrogen three times, ending with the flask under nitrogen. Acetonitrile (3.5 ml) was added to the flask, which was then covered with aluminium foil. The reaction was heated to 333 K and stirred under a nitrogen atmosphere for 12 h. The reaction was cooled to room temperature and the solvent then removed under vacuum. The crude product was dissolved in a minimal amount of THF and recrystallized by slow diffusion of pentane into the solution. These recrystallization conditions performed on a smaller scale produced the yellow block-like crystals used for X-ray crystallographic analysis. IR ν_{CO} (KBr pellet, cm⁻¹): 2072(*s*), 1977(*s*), 1936(*s*).

7. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 3. For both compounds the C-bound H atoms were included in idealized positions and allowed to ride on the parent atoms: C—H = 0.95–0.99 Å with $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$. In compound II, the carboxylic H atom was located in a difference-Fourier map and freely refined.

In compound I, the benzoic acid fragment is disordered over two positions with the major component contribution of

74.8 (3)%. The disordered fragment was refined with restraints. The solvent THF molecule is disordered over at least three positions. Bond-length restraints were applied to model the molecules but the resulting isotropic displacement coefficients suggested they were mobile. In addition, the refinement was computationally unstable. Finally the option SQUEEZE of the program *PLATON* (Spek, 2015) was used to correct the diffraction data for diffuse scattering effects and to identify the solvate molecule. *PLATON* calculated the upper limit of volume that can be occupied by the solvent to be 475 Å³, or 21% of the unit-cell volume. The program calculated 153 electrons in the unit cell for the diffuse species. This closely corresponds to four molecules of THF (160 electrons) per unit cell, or one THF molecule per Mn¹ complex (**I**). Their formula mass and unit-cell characteristics were not taken into account during refinement. It is very likely that this solvate molecule, which is disordered over several positions, could form hydrogen bonds.

In compound **II**, the THF molecule is disordered over three positions in a 0.672 (3):0.202 (2):0.126 (3) ratio. The disordered molecules were refined with restraints and constraints (Guzei, 2014).

Crystal structures of a manganese(I) and a rhenium(I) complex of a bipyridine ligand with a non-coordinating benzoic acid moiety

Sheri Lense, Ilia A. Guzei, Jessica Andersen and Kong Choua Thao

Computing details

For both structures, data collection: *APEX3* (Bruker, 2015); cell refinement: *SAINT-Plus* (Bruker, 2015); data reduction: *SAINT-Plus* (Bruker, 2015); program(s) used to solve structure: *SHELXT* (Sheldrick, 2015a); program(s) used to refine structure: *SHELXL* (Sheldrick, 2015b); molecular graphics: *OLEX2* (Dolomanov *et al.*, 2009) and *Mercury* (Macrae *et al.*, 2008); software used to prepare material for publication: *OLEX2* (Dolomanov *et al.*, 2009) and *PLATON* (Spek, 2009).

fac-Bromido[2-(2,2'-bipyridin-6-yl)benzoic acid- κ^2N,N']tricarbonylmanganese(I) tetrahydrofuran monosolvate (I)

Crystal data

$[\text{MnBr}(\text{C}_{17}\text{H}_{12}\text{N}_2\text{O}_2)(\text{CO})_3]\cdot\text{C}_4\text{H}_8\text{O}$
 $M_r = 495.17$
Monoclinic, $P2_1/n$
 $a = 10.525$ (3) Å
 $b = 18.187$ (5) Å
 $c = 12.459$ (4) Å
 $\beta = 105.928$ (13)°
 $V = 2293.2$ (12) Å³
 $Z = 4$

$F(000) = 984$
 $D_x = 1.434 \text{ Mg m}^{-3}$
Mo $K\alpha$ radiation, $\lambda = 0.71073$ Å
Cell parameters from 9894 reflections
 $\theta = 2.2\text{--}28.9^\circ$
 $\mu = 2.35 \text{ mm}^{-1}$
 $T = 100$ K
Needle, yellow
0.21 × 0.04 × 0.03 mm

Data collection

Bruker SMART APEXIII area detector
diffractometer
Radiation source: microfocus sealed X-ray tube,
Incoatec I μ s
Mirror optics monochromator
Detector resolution: 7.9 pixels mm⁻¹
0.5° ω and 0.5° φ scans
Absorption correction: multi-scan
(SADABS; Krause *et al.*, 2015)

$T_{\min} = 0.673$, $T_{\max} = 0.802$
51901 measured reflections
6992 independent reflections
5393 reflections with $I > 2\sigma(I)$
 $R_{\text{int}} = 0.048$
 $\theta_{\max} = 30.6^\circ$, $\theta_{\min} = 2.0^\circ$
 $h = -15 \rightarrow 15$
 $k = -26 \rightarrow 25$
 $l = -17 \rightarrow 17$

Refinement

Refinement on F^2
Least-squares matrix: full
 $R[F^2 > 2\sigma(F^2)] = 0.041$
 $wR(F^2) = 0.104$
 $S = 1.01$
6992 reflections

346 parameters
149 restraints
Primary atom site location: dual
Hydrogen site location: inferred from
neighbouring sites
H-atom parameters constrained

$$w = 1/[\sigma^2(F_o^2) + (0.0415P)^2 + 3.4283P]$$

where $P = (F_o^2 + 2F_c^2)/3$
 $(\Delta/\sigma)_{\max} = 0.001$

$$\Delta\rho_{\max} = 0.59 \text{ e } \text{\AA}^{-3}$$

$$\Delta\rho_{\min} = -0.76 \text{ e } \text{\AA}^{-3}$$

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

Fractional atomic coordinates and isotropic or equivalent isotropic displacement parameters (\AA^2)

and constrained refinement $w = 1/[\sigma^2(F_o^2) + (0.0182P)^2 + 2.0257P]$ where $P = (F_o^2 + 2F_c^2)/3$ $(\Delta/\sigma)_{\max} = 0.003$ $\Delta\rho_{\max} = 1.63$ e Å⁻³ $\Delta\rho_{\min} = -1.64$ e Å⁻³*Special details*

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

Fractional atomic coordinates and isotropic or equivalent isotropic displacement parameters (Å²)
