The crystal structures of $\text{Na}_2\text{SeO}_4 \cdot 1.5\text{H}_2\text{O}$ (sodium selenate sesquihydrate) and $\text{Na}_2\text{SeO}_4 \cdot 10\text{H}_2\text{O}$ (sodium selenate decahydrate) are isotopic with those of $\text{Na}_2\text{CrO}_4 \cdot 1.5\text{H}_2\text{O}$ and $\text{Na}_2\text{XSeO}_4 \cdot 10\text{H}_2\text{O}$ ($\text{X} = \text{S}, \text{Cr}$), respectively. The asymmetric unit of the sesquihydrate contains two Na^+ cations, one SeO_4 tetrahedron and one and a half water molecules, the other half being generated by twofold rotation symmetry. The coordination polyhedra of the cations are a distorted monocapped octahedron and a square pyramid; these $[\text{NaO}_x]$ polyhedra are linked through common edges and corners into a three-dimensional framework structure, the voids of which are filled with the Se atoms of the SeO_4 tetrahedra. The structure is consolidated by $\text{O}-\text{H}\cdots\text{O}$ hydrogen bonds between coordinating water molecules and framework O atoms. The asymmetric unit of the decahydrate consists of two Na^+ cations, one SeO_4 tetrahedron and ten water molecules. Both Na^+ cations are octahedrally surrounded by water molecules and by edge-sharing condensed into zigzag chains extending parallel to [001]. The SeO_4 tetrahedra and two uncoordinating water molecules are situated between the chains and are connected to the chains through an intricate network of medium-strength $\text{O}-\text{H}\cdots\text{O}$ hydrogen bonds.

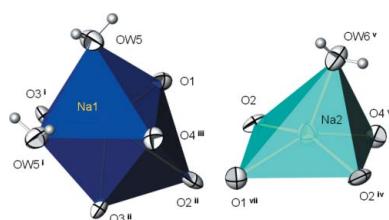

1. Chemical context

Based on recent studies in the system Na/Se/O/H that revealed dimorphism of the phases NaHSeO_4 and $\text{Na}_5\text{H}_3(\text{SeO}_4)_4 \cdot (\text{H}_2\text{O})_2$ (Pollitt & Weil, 2014), we became interested in the structure determination of hydrous phases of Na_2SeO_4 . Although the first report of the decahydrate of Na_2SeO_4 dates back to 1827 (Mitscherlich, 1827), a detailed structure report for this compound has not been published so far. Mitscherlich (1827) also recognized an isomorphic relationship of $\text{Na}_2\text{SeO}_4 \cdot 10\text{H}_2\text{O}$ with $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$ (Glauber's salt or mirabilite as a mineral species). This relation was later confirmed by Rosicky (1908) and by Ruben *et al.* (1961) on the basis of unit-cell determinations using diffraction methods. Another hydrous phase of Na_2SeO_4 reported in the literature is the metastable heptahydrate that crystallized from supersaturated Na_2SeO_4 solutions only when seeded with $\text{Na}_2\text{SO}_4 \cdot 7\text{H}_2\text{O}$ nuclei below 293 K (Belarew, 1965).

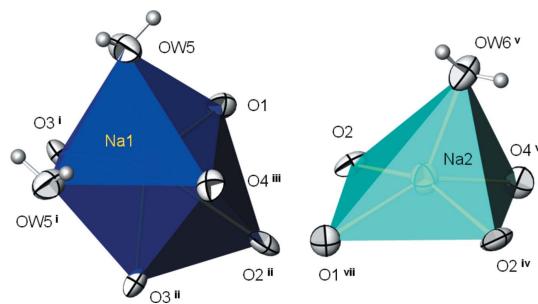

During crystallization studies of aqueous Na_2SeO_4 solutions under different temperature conditions, we were able to isolate crystals not only of the decahydrate, but also of the sesquihydrate, the crystal structures of which are reported here.

2. Structural commentary

$\text{Na}_2\text{SeO}_4 \cdot 1.5\text{H}_2\text{O}$ is isotopic with the corresponding chromate (Kahlenberg, 2012) and is the second example of the

$\text{Na}_2\text{XO}_4 \cdot 1.5\text{H}_2\text{O}$ structure family. The main building blocks of this structure type are distorted $[\text{NaO}_5(\text{H}_2\text{O})_2]$ ($\text{Na}1$) monocapped octahedra, distorted $[\text{NaO}_4(\text{H}_2\text{O})]$ square pyramids ($\text{Na}2$) (Fig. 1) and rather regular XO_4 ($\text{X} = \text{Se, Cr}$) tetrahedra. These building blocks are linked through common corners and edges into a three-dimensional framework structure (Fig. 2). Hydrogen bonds of the type $\text{O}-\text{H}\cdots\text{O}$ between the coordinating water molecules and parts of the framework O atoms provide additional stabilization (Table 1). The bond lengths (Table 2) and angles within the individual building blocks of

$\text{Na}2-\text{O}2$	2.298 (2)	$\text{Se}1-\text{O}1$	1.6481 (15)

Symmetry codes: (i) $x + \frac{1}{4}, y + \frac{1}{4}, -z + \frac{1}{4}$; (ii) $x + \frac{1}{2}, y + \frac{1}{2}, z$; (iii) $x + 1, y, z$; (iv) $x - \frac{1}{2}, -y, -z + \frac{1}{2}$; (v) $x - 1, y, z$; (vi) $x, -y + \frac{1}{2}, -z + \frac{1}{2}$; (vii) $x - \frac{1}{2}, y - \frac{1}{2}, z$.

the selenate and chromate structures are more or less identical with mean distances of $\text{SeO}_4 = 1.641$; $\text{CrO}_4 = 1.651$; $\text{NaO}_7 = 2.514$ (selenate), 2.505 (chromate); $\text{NaO}_5 = 2.350$ (selenate), 2.360 \AA (chromate).

Isotypism has been reported for several $\text{Na}_2\text{XO}_4 \cdot 10\text{H}_2\text{O}$ ($\text{X} = \text{S, Se, Cr, W, Mo}$) phases (Ruben *et al.*, 1961), but only the structures of $\text{X} = \text{S}$ (Levy & Lisensky, 1978; Prescott *et al.*, 2001) and Cr (Kahlenberg, 2012) have been determined so far. As expected, the general structural set-up in the isotropic $\text{Na}_2\text{XO}_4 \cdot 10\text{H}_2\text{O}$ structures is very similar. Each of the two Na^+

**Figure 3**

cations is octahedrally surrounded [mean Na—O distance of the two octahedra is 2.420 \AA (see Table 3); sulfate analogue (Prescott *et al.*, 2001): 2.415 \AA ; chromate analogue (Kahlenberg, 2012): 2.423 \AA]. The $[\text{NaO}_6]$ octahedra are linked via edge-sharing into zigzag chains (Fig. 3) running parallel to [001]. These chains are linked with neighbouring chains and intermediate SeO_4 tetrahedra (mean Se—O distance 1.639; sulfate 1.488, chromate 1.647 \AA) and non-coordinating lattice water molecules through O—H···O hydrogen bonds of medium strength (Table 4) to build up the crystal structure (Fig. 4). The most important difference between the structures of the three $\text{Na}_2\text{XO}_4 \cdot 10\text{H}_2\text{O}$ ($\text{X} = \text{S, Se, Cr}$) phases is the missing disorder of the XO_4 tetrahedron in the selenate compound that has been observed in the sulfate compound on the basis of single-crystal neutron data (Levy & Lisenky, 1978) and single-crystal X-ray data (Prescott *et al.*, 2001), or for the chromate compound on the basis of single-crystal X-ray data (Kahlenberg, 2012).

3. Synthesis and crystallization

Anhydrous Na_2SeO_4 was prepared according to the method compiled by Brauer (1963) by adding a half-concentrated aqueous selenic acid solution (*ca* 60 wt%) to an excess of an Na_2CO_3 solution. The resulting solution was heated until a

considerable amount of the neutralization product had crystallized. The crystal mush was then separated by suction filtration of the still-hot solution and dried in air. X-ray powder diffraction revealed a single-phase material. The Na_2SeO_4 crystals were then dissolved in small amounts of water and kept at *ca* 300, 293 and 280 K until complete evaporation of the solvent. According to Rietveld refinements using TOPAS (Bruker, 2013) the product crystallized at 300 K consisted of Na_2SeO_4 and $\text{Na}_2\text{SeO}_4 \cdot 1.5\text{H}_2\text{O}$ in an approximate 9:1 weight ratio, the product crystallized at 290 K consisted of Na_2SeO_4 and $\text{Na}_2\text{SeO}_4 \cdot 1.5\text{H}_2\text{O}$ in an approximate 5:1 ratio, and the product crystallized at 280 K consisted of Na_2SeO_4 , $\text{Na}_2\text{SeO}_4 \cdot 1.5\text{H}_2\text{O}$ and $\text{Na}_2\text{SeO}_4 \cdot 10\text{H}_2\text{O}$ in an approximate 5:4:1 ratio. The crystal forms of the three obtained phases were different and were used for separation. Crystals of the anhydrous phase had mainly a lath-like form, of the sesquihydrate a plate-like form, and of the decahydrate a pinacoidal form. All obtained hydrate phases tend to weather when stored under ambient conditions.

4. Refinement

Unit-cell determinations revealed isotopic relationships with the corresponding chromate phases (Kahlenberg, 2012). For better comparison of the isotopic structures, atom labels and the setting of the unit cells of the selenate compounds were retained, and the coordinates of the non-H atoms of the chromate structure were used as starting parameters for refinement [note that the unit cell of $\text{Na}_2\text{CrO}_4 \cdot 1.5\text{H}_2\text{O}$ is given in the non-standard setting $F2dd$ of space group No. 43 (standard setting $Fdd2$)]. The H atoms of the water molecules were located from difference maps and were refined with a common U_{iso} parameter and a fixed O—H distance of 0.82 \AA . Experimental details are given in Table 1.

neighbouring sites

H-atom parameters constrained

$$w = 1/[\sigma^2(F_o^2) + (0.0148P)^2]$$

where $P = (F_o^2 + 2F_c^2)/3$

$$(\Delta/\sigma)_{\max} < 0.001$$

$$\Delta\rho_{\max} = 0.91 \text{ e \AA}^{-3}$$

$$\Delta\rho_{\min} = -0.37 \text{ e \AA}^{-3}$$

Absolute structure: Flack (1983), 823 Friedel pairs

Absolute structure parameter: 0.025 (8)

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.

where $P = (F_o^2 + 2F_c^2)/3$ $(\Delta/\sigma)_{\max} = 0.006$ $\Delta\rho_{\max} = 0.48 \text{ e } \text{\AA}^{-3}$ $\Delta\rho_{\min} = -0.52 \text{ e } \text{\AA}^{-3}$

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
