Received 3 June 2014; accepted 9 June 2014

Edited by W. T. A. Harrison, University of Aberdeen, Scotland

The crystal structure of the room-temperature modification of $\text{K}[\text{Hg}(\text{SCN})_3]$, potassium trithiocyanatomercurate(II), was redetermined based on modern CCD data. In comparison with the previous report [Zhdanov & Sanadze (1952). *Zh. Fiz. Khim.* **26**, 469–478], reliability factors, standard deviations of lattice parameters and atomic coordinates, as well as anisotropic displacement parameters, were revealed for all atoms. The higher precision and accuracy of the model is, for example, reflected by the Hg–S bond lengths of 2.3954 (11), 2.4481 (8) and 2.7653 (6) Å in comparison with values of 2.24, 2.43 and 2.77 Å. All atoms in the crystal structure are located on mirror planes. The Hg^{2+} cation is surrounded by four S atoms in a seesaw shape [S–Hg–S angles range from 94.65 (2) to 154.06 (3)°]. The HgS_4 polyhedra share a common S atom, building up chains extending parallel to [010]. All S atoms of the resulting $\infty[\text{HgS}_{2/1}\text{S}_{2/2}]$ chains are also part of SCN[−] anions that link these chains with the K⁺ cations into a three-dimensional network. The K–N bond lengths of the distorted KN₇ polyhedra lie between 2.926 (2) and 3.051 (3) Å.

Keywords: crystal structure; redetermination; phase transition; mercury.

CCDC reference: 1006909

1. Related literature

$\text{K}[\text{Hg}(\text{SCN})_3]$ has been determined originally in the space group $P2_1/m$ with $Z = 8$, based on room-temperature data (Zhdanov & Sanadze, 1952). A subsequent redetermination revealed a doubled unit cell in $P2_1/n$, $Z = 4$, based on intensity data measured at 150 K (Bowmaker *et al.*, 1998).

However, there is no report on an apparent phase transition of $\text{K}[\text{Hg}(\text{SCN})_3]$ between these two temperatures. For symmetry relationships between crystal structures, see: Müller (2013).

Crystal structure of K[Hg(SCN)₃] – a redetermination

Matthias Weil and Thomas Häusler

S1. Experimental

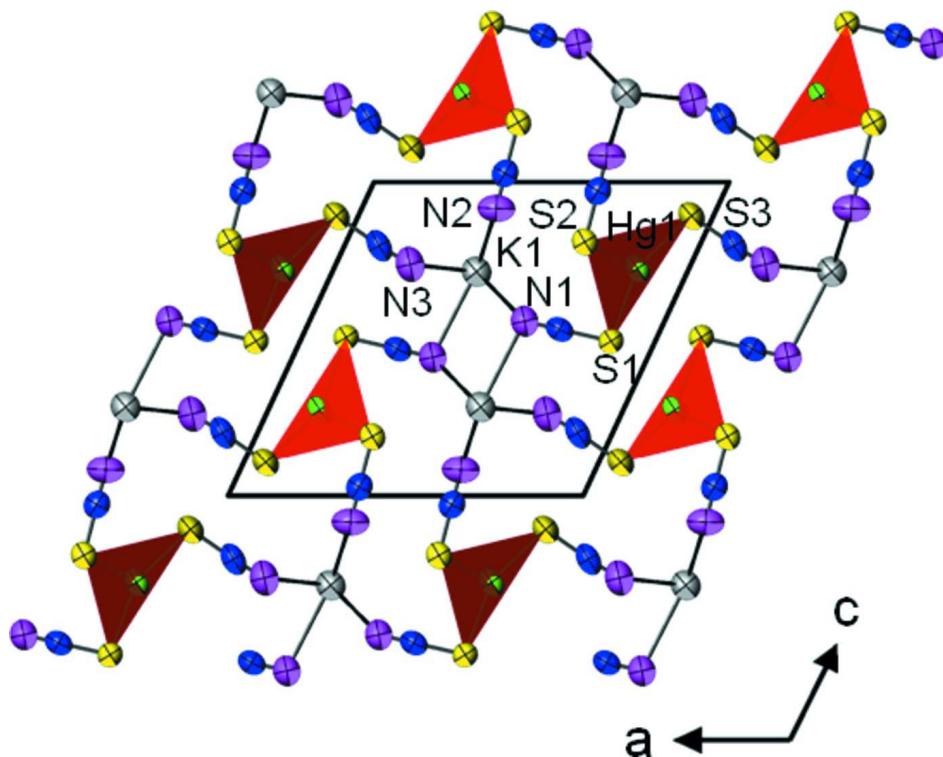

Hg(SCN)₂ (0.5 g) was dissolved under heating in a water–ethanol mixture (1:1 *v/v*) to which KSCN (0.1 g) was added. After one week, colourless crystals with a lath-like form were obtained from the remaining solution.

S2. Refinement

For better comparison with the previous determination by Zhdanov & Sanadze (1952), the original nonreduced cell setting as well as the atom labelling and the atomic coordinates were used as starting parameters for the refinement.

Bowmaker *et al.* (1998) reported a doubled unit cell for K[Hg(SCN)₃] with $a = 11.9119$ (3), $b = 4.0201$ (1), $c = 18.7095$ (3) Å, $\beta = 91.852$ (1)°, $P2_1/n$, $Z = 4$. However, no superstructure reflections were found in the current redetermination at 293 K, while Bowmaker *et al.* (1998) used intensity data measured at 150 K. Therefore it appears likely that K[Hg(SCN)₃] has a phase transition between these two temperatures. The two unit cells of the room-temperature phase in $P2_1/m$ and the low-temperature phase in $P2_1/n$ are related by the matrix (101,010,101), revealing a *klassengleiche* symmetry reduction of index 2 (Müller, 2013).

The highest and lowest electron densities are found 0.66 and 0.28 Å, respectively, from atom S3.

**Figure 1**

The crystal structure of $\text{K}[\text{Hg}(\text{SCN})_3]$ in a projection along [010]. Displacement ellipsoids are drawn at the 90% probability level. Colour code: Hg green, S yellow, C blue, N magenta, K grey. The HgS_4 polyhedron is shown in red.

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
