(Received March 3, 2008; Accepted May 16, 2008)

Key Words—Bacteroidetes; homospermidine; polyamine; spermidine

Cellular polyamine profiles as a phenotypic chemotaxonomic marker within the phylum Bacteroidetes, which is divided into the three classes (orders) Bacteroidetes (Bacteroidales), Flavobacteria (Flavobacteriales) and Sphingobacteria (Sphingobacteriales) have been studied (Hamana and Matsuzaki, 1990, 1991; Hamana and Nakagawa, 2001a, b; Hamana and Niiitsu, 2001; Hamana et al., 1995; Hosoya and Hamana, 2003, 2004). Our previous analyses revealed that most of the strains examined in the classes Bacteroidetes and Flavobacteria contained two triamines, spermidine and homospermidine, respectively, as major polyamine components; however, the polyamine profiles over the two classes remain to be elucidated with sizable number of species. On the other hand, the polyamine profiles in the class Sphingobacteria are variable depend on genera or families. In the present study, 105 new strains belonging to the phylum Bacteroidetes were analyzed to survey the distribution of spermidine, homospermidine and other polyamines to evaluate their chemotaxonomic significance.

The strains examined were cultured anaerobically at optimum growth temperature (30–37°C) in GAM Broth (Nissui Pharmaceutical Co., Tokyo, Japan), using An-

aerobic Jar KJ-1 (Tomy Seiko, Tokyo) (Hamana et al., 1995), or aerobically at 25–30°C in Marine Broth (DIFCO, MI, USA), Marine Agar, Trypticase Soy Broth (BBL, MD, USA), polyamine-free Synthetic 199 Medium dissolved in seawater (199-SW) and various media listed in ATCC, JCM and NBRC (ATCC website, 2008; JCM website, 2008; NBRC website, 2008). Cells in the stationary growing phase were harvested from a 50–100 ml liquid culture by centrifugation at 3,000×g and washed with an isotonic saline or PBS (Nissui Pharmaceutical Co.). The anaerobic strains grown on blood agar plates were raked from the plates. The cell pellets were homogenized in equal volumes of cold 1.0 M perchloric acid (PCA). Polyamines extracted into 0.5 M PCA were analyzed by high performance liquid chromatography (HPLC) on a Hitachi L6000 high-speed liquid chromatograph using a column of cation-exchange resin (Hamana, 2002; Hamana et al., 1995). When a low polyamine level was detected in the PCA extracts, the PCA extracts from a large-scale culture (1 L) were subjected to a cation-exchange Dowex-50W column (Hamana, 2002), and then the concentrated polyamine fractions were analyzed by HPLC.

Class Bacteroidetes (Order Bacteroidales): The class Bacteroidetes is phylogenetically divided into four families, Bacteroidaceae, Porphylobacteraceae, Prevotellaceae and Rikenellaceae (Boone and Castenholz, 2001; Sakamoto, 2007; NCBI website, 2008). Spermidine has been detected as the major polyamine

in the six genera, *Bacteroides*, *Dysgomononas*, *Prevotella*, *Porphylomonas*, *Tannerella* and *Marinilabilia* (Hosoya and Hamana, 2004). In the present study on the family Bacteroidaceae, spermidine was found ubiquitously in the new 12 species of the genus *Bacteroides* and an anaerobe, *Anaerorhabdus furcosa* (Table 1), in addition to the authentic 11 *Bacteroides* species previously analyzed (Hosoya and Hamana, 2004). *Megamonas hypermegae*, transferred recently in the phylum Firmicutes (Morotomi et al., 2007), contained cadaverine as a major polyamine (Table 1). 2-Phenylethylamine was found in *B. coprophiles* (Table 1); however, the chemotaxonomic significance of the occurrence of the aromatic amine is not clear. In the family Porphyromonadaceae, the *Barnesiella*, *Dysgomononas*, *Parabacteroides*, *Paludibacter*, *Porphylomonas* and *Tannerella* species analyzed here, contained spermidine as the major triamine (Table 1). The major polyamine of the other five *Porphylomonas* species was spermidine (Hosoya and Hamana, 2004). A species of the genus *Hallella* and 14 new species of the genus *Prevotella* belonging to the family Prevotellaceae, analyzed in the present study, ubiquitously contained spermidine (Table 1). Spermidine has been detected in 13 other species of *Prevotella* reported in our previous study (Hosoya and Hamana, 2004). *Alistipe putredinis* (formerly *Bacteroides putredinis*) and *Marinilabilia salmonicolor* contained spermidine (Hosoya and Hamana, 2004). *Rikenella microfusus* containing homospermidine, located in the fourth family, Rikenellaceae, was unique in the polyamine profiles within the class Bacteroidetes (Hosoya and Hamana, 2004).

Class Flavobacteria (Order Flavobacterales): *Crocinitomix catalastica* and *Owenweeksia hongkongensis*, which are located in the family Cryomorphaceae (Bernardet et al., 2002; Nakagawa, 2004; NCBI website, 2008), contained homospermidine as the major triamine (Table 1). Homospermidine has been found as the major polyamine in various genera located in the family Flavobacteriaceae (Hamana and Matsuzaki, 1990, 1991; Hamana and Nakagawa, 2001a, b). The mesophilic, slightly halophilic 42 flavobacteria belonging to the recently validated 18 new genera of the family, analyzed in the present study, ubiquitously contained homospermidine (Table 1). Spermidine detected in some species is a minor contaminant from polyamine-containing media used for their cultures. Cadaverine, agmatine, and 2-phenylethylamine have been found sporadically (Hamana and Niitsu, 2001;

Hosoya and Hamana, 2003, 2004). In the previous studies, homospermidine was the major polyamine in 9 other genera, *Bergeyella*, *Empedobacter*, *Gelidibacter*, *Myroides*, *Ornithobacterium*, *Polaribacter*, *Psychroserpens*, *Riemerella*, and *Weeksella* of this family (Hamana and Nakagawa, 2001a, b).

Class Sphingobacteria (Order Sphingobacterales): In our previous studies, no significant amount of triamines was detected in *Flammeovirga aprica* or *Flammeovirga arenaria* (formerly *Microscilla arenaria*) (Hosoya and Hamana, 2003; Nakagawa et al., 1997). The polyamine analysis of the three new species, *F. yaeyamensis*, *F. kamogawensis* and *Flammeovirga* sp. (Hosoya and Yokota, 2007; Takahashi et al., 2006) and *Sediminitorumix flava* (Khan et al., 2007), belonging to the family Flammeovirgaceae, grown in MA, MB and/or polyamine-free 199-SW media, showed a novel triamine-absent profile (Table 1). Low spermidine levels observed in the MA and MB cultures may be derived from the spermidine-containing media. The cellular levels of putrescine, cadaverine and agmatine as a minor polyamine component might be changed by their growth conditions. The absence of triamines in these organisms is unique within this family, and furthermore, within the class Sphingobacteria and the phylum Bacteroidetes. *Rapidithrix* and *Pereolibacter* analyzed here (Table 1) and *Flexithrix* and *Persicobacter* analyzed previously (Hamana and Nakagawa, 2001a, b; Hamana et al., 1995; Nakagawa et al., 1997), belonging to this family, contained spermidine as the major triamine. Slightly/moderately thermophilic *Thermonema lapsum* containing homospermidine (Hamana et al., 1992) is unique in this family. Spermine (a tetra-amine) and thermopentamine (a penta-amine) found in moderately thermophilic *Acetomicrumbium flavidum* (grown at 60°C) of the class Bacteroidetes (Hamana, 1999) were not detected in the slight/moderate thermophile grown at 60°C. Two types of cellular triamine component were observed in the family Flexibacteraceae, suggesting that the family is a chemotaxononomically heterogeneous group. *Algoriphagus*, *Cyclobacterium*, *Flexibacter* and *Hongiella* contained homospermidine, whereas *Dyadobacter*, *Flectobacillus*, *Microscilla*, *Persicitalea* and *Reichenbachiella* contained spermidine (Table 1). In the family Saprosiraceae, *Haliscomenobacter* and *Lewinella* species (Hamana and Nakagawa, 2001a) and *Aureispira marina* analyzed in the present study (Table 1), contained spermidine. *Saprosira grandis* containing agmatine as the

Put, putrescine; Cad, cadaverine; Spd, spermidine; HSpd, homospermidine; Spm, spermine; Agm, agmatine; Pea, 2-phenylethylamine; ATCC, American Type Culture Collection, Manassas, Virginia, USA; IAM, IAM Culture Collection, Institute of Molecular and Cellular Biosciences, The University of Tokyo, Tokyo, Japan; IFO, Institute for Fermentation, Osaka, Japan; JCM, Japan Collection of Microorganisms, RIKEN, Saitama, Japan; NBRC, Biological Resource Center, National Institute of Technology and Evaluation, Kisarazu, Japan; NCIMB, The National Collection of Industrial, Marine and Food Bacteria, Aberdeen, Scotland, UK; ^T, type strain; —, not detected (<0.005). Data were obtained from single samples. Former names are shown in parentheses. Double quotation marks show that the scientific name has not been validated. (MA), (MB) and (199-SW), cultured in Marine Agar, Marine Broth, and polyamine-free Synthetic 199 Medium dissolved in seawater, respectively. (a) Cited from Hamana, 1999. (b) Hosoya and Hamana, 2004. (c) Hamana et al., 1995. (d) Hamana and Nakagawa, 2001a. (e) Hosoya and Hamana, 2003. (f) Hamana et al., 1992. (g) Hamana et al., 1998. (h) Hamana and Niitsu, 2001. (i) Hamana and Nakagawa, 2001b. Penta-amines and hexa-amines found in the thermophiles, *Acetomicrobium flavidum* and *Rhodothermus marinus*, previously reported, were omitted in the table.

major polyamine, lacks tiamine synthetic ability (Hamana and Nakagawa, 2001a) and is unique within the phylum Bacteroidetes. The polyamine distribution pattern of the new genus *Roseivirga* of the family Sphingobacteriaceae shows a novel profile containing spermidine and homospermidine (Table 1). Six new species of *Pedobacter* (Table 1) and *P. heparinus*, *P. piscium* and 6 species of *Sphingobacterium* analyzed previously (Hamana and Nakagawa, 2001b), contained ho-

mospermidine. In the tentative family "Crenotrichaceae" (Anton et al., 2002; Mongodin et al., 2005; Pena et al., 2005; Soria-Carrasco et al., 2007), homospermidine has been known as the major polyamine of *Chitinophaga* species (Hamana and Nakagawa, 2001a). The low spermidine and homospermidine concentrations in a novel mesophilic, extremely halophilic *Salinibacter ruber*, are agreement with another report on the cellular polyamines of this organism (Pena et al., 2005).

The polyamine catalogue differ from the observations for extremely halophilic archaebacteria consisting the order Halobacterales (Tanaka et al., 2002) and the moderately halophilic eubacterial order Halanaerobiales of the phylum Firmicutes (Hosoya et al., 2006). Homospermidine was not found whereas low spermidine and/or spermine levels were detected in the orders Halobacterales and Halanaerobiales. The rRNA sequences of *S. ruber* most closely related to the slightly halophilic, extremely thermophilic genus *Rhodothermus*, but the polyamine profile was markedly differentiated between *S. ruber* and *R. marinus* (Hamana et al., 1992, 1998). *R. marinus* grown at 70°C contained spermidine, spermine, thermopentamine and branched N⁴-bis(aminopropyl)spermidine, indicating that the occurrence of the tetra-amine and penta-amines correlate to its extremely thermophily (Hamana et al., 1992, 1998).

Acknowledgments

We are indebted to ATCC, JCM, IAM and NBRC for supplying bacterial strains and Dr. A. Yokota (IAM) and Dr. Y. Nakagawa (NBRC) for valuable advice and encouragement.
