**1. Project Overview**

The LINPACK Benchmark has been used as a yardstick in measuring the performance of the Top500 installed high-end computers. This benchmark was chosen because it is widely used and performance numbers are available for almost all relevant systems. The approach used in the LINPACK Benchmark is to solve a dense system of linear equations. For the Top500, the benchmark allows the user to scale the size of the problem and to optimize the software in order to achieve the best performance for a given machine. This performance does not reflect the overall performance of a given system, as no single number ever can. It does, however, reflect the performance of a dedicated system for solving a dense system of linear equations. Since the problem is very regular, the performance achieved is quite high, and the performance numbers give a good check of peak performance of a system.

By measuring the actual performance for different problem sizes  $n$ , a user can get not only the maximal achieved performance  $R_{\max}$  for the problem size  $N_{\max}$  but also the problem size  $N_{1/2}$  where half of the performance  $R_{\max}$  is achieved. These numbers together with the theoretical peak performance  $R_{\text{peak}}$  are the numbers given in the Top500. In an attempt to obtain uniformity across all computers in performance reporting, the algorithm used in solving the system of equations must conform to the standard operation count for LU factorization with partial pivoting. In particular, the operation count for the algorithm must be  $\frac{2}{3} n^3 + O(n^2)$  floating point operations.

**2. Papers and Book Chapters Supported in Part by the Subcontract**

None

**3. Project Highlight**

As part of this proposal we developed a version of the Benchmark based on the hardware of the ASCI BLUE Pacific system to achieve high performance. It was our goal to produce the fastest implementation that will take advantage of the hardware and software infrastructure on the BLUE Pacific machine in achieving this mark. In order to accomplish this goal, our team drew on the expertise in this field developed with our work on the ScaLAPACK and ATLAS projects. We collaborated with researchers at LLNL to produce software for the Linpack benchmark that is fully optimized for the ASCI-Blue Pacific system.

The ATLAS project involves using timings coupled with code generation to automatically adapt linear algebra computations to run optimally on varying

architectures. The expertise developed in this project will be leveraged in order to make machine-specific performance tweaks for the computations involved in the benchmark. In particular, tunings for various levels of caches, floating point register and unit usage, and optimal use of threading. We presented a tutorial at LLNL on the ATLAS optimization implementation and described ways to optimize numerical software in general.

#### 4. Concluding Remarks

Some of this work is on going with LLNL researchers.
