Key Words. Physician survey • Chemotherapy-induced nausea and vomiting • Antiemetic guidelines • Guideline adherence

ABSTRACT

Background. Guideline-recommended antiemetic prophylaxis improves nausea and vomiting control in most patients undergoing chemotherapy. Multinational Association of Supportive Care in Cancer/European Society for Medical Oncology (MASCC/ESMO) antiemetic guidelines recommend prophylaxis with a neurokinin-1 receptor antagonist (NK₁RA), a 5-hydroxytryptamine-3 receptor antagonist (5-HT₃RA), and dexamethasone for patients receiving highly emetogenic chemotherapy (HEC), including anthracycline-cyclophosphamide (AC)- and carboplatin (considered moderately emetogenic chemotherapy)-based chemotherapy. Here, we analyze the use of NK₁RA–5-HT₃RA–dexamethasone for antiemetic prophylaxis associated with HEC and carboplatin.

Methods. The data source was the Global Oncology Monitor (Ipsos Healthcare). Geographically representative physicians from France, Germany, Italy, Spain, and the U.K. were screened for treatment involvement and number of patients treated per month. Patients' data from January to December 2018 were collected from medical charts and extrapolated on the basis of the total number of physicians

who prescribe chemotherapy. The emetic risk of chemotherapy was classified per MASCC/ESMO guidelines.

Results. Data from 45,324 chemotherapy-treated patients were collected, representing a total extrapolated prevalence of 1,394,848 chemotherapy treatments included in the analysis. NK₁RA were used in 45%, 42%, and 19% of patients receiving cisplatin-, AC-, and carboplatin-based chemotherapy, respectively; 18%, 24%, and 7% received the guideline-recommended NK₁RA–5-HT₃RA–dexamethasone combination; no antiemetics were prescribed for 12% of the treatments. Often, physicians' perception of the emetic risk of chemotherapy did not follow MASCC/ESMO guideline classification.

Conclusion. Low adherence to antiemetic guidelines was revealed in clinical practice in five European countries, with 15% of all HEC/carboplatin-based treatments receiving guideline-recommended NK₁RA–5-HT₃RA–dexamethasone prophylaxis and 12% of them receiving no antiemetics. New strategies for improving guideline adherence are urgently needed. *The Oncologist* 2021;26:e1073–e1082

Implications for Practice: Despite recent advances in antiemetic therapy, a substantial proportion of patients experience nausea and vomiting associated with chemotherapy in daily clinical practice. Antiemetic guidelines aim at prevention of chemotherapy-induced nausea and vomiting (CINV), and guideline-consistent antiemetic therapy can effectively prevent vomiting and, to a lesser extent, nausea in most patients with cancer. This study reports low adherence to antiemetic guidelines in the highly emetogenic chemotherapy setting in daily clinical practice across five European countries. Opportunity

exists to increase adherence to antiemetic guideline recommendations. Implementation of strategies to facilitate guideline adherence can potentially improve CINV control.

INTRODUCTION

Chemotherapy-induced nausea and vomiting (CINV) is ranked by patients among the most distressing and persistent side effects of specific anticancer treatments [1, 2] and can negatively affect quality of life of patients with cancer [3]. In some instances, failure to correctly manage CINV can prevent patients from completing chemotherapy [4]. Monitoring of common chemotherapy-related symptoms, such as nausea and vomiting, among others, through electronic patient-reported outcomes, and their management has been shown to increase overall survival [5, 6]. Early intervention for symptom control to prevent further unfavorable effects, and the ability of patients to tolerate chemotherapy treatments for longer periods, have been hypothesized to be responsible for the increased survival effects.

According to the time of occurrence after chemotherapy administration, CINV is classified into acute (occurring within the first 24 hours), delayed (between 24 and 120 hours), and overall (between 0 and 120 hours) categories [7].

Chemotherapeutic agents are ranked in international antiemetic guidelines on the basis of the probability for inducing acute emesis in the absence of antiemetic prophylaxis into highly emetogenic chemotherapy (HEC), moderately emetogenic chemotherapy (MEC), low emetogenic chemotherapy (LEC), and minimally emetogenic chemotherapy. HEC, which is associated with a > 90% risk for emesis, includes agents such as cisplatin and the anthracycline-cyclophosphamide (AC) combination [8, 9], and MEC, which is correlated with a 30%–90% emetic risk, encompasses agents such as carboplatin, oxaliplatin, cytarabine, and ifosfamide, among others [8, 9]. Agents' classification is revised periodically on the basis of new clinical data. Although antiemetic guidelines of the Multinational Association of Supportive Care in Cancer/European Society for Medical Oncology (MASCC/ESMO) [10, 11] still classify carboplatin-based regimens as MEC, they consider them as HEC for their antiemetic recommendations.

MASCC/ESMO antiemetic guidelines [10, 11] recommend prophylaxis with a 5-hydroxytryptamine-3 receptor antagonist (5-HT₃RA) plus dexamethasone for patients treated with MEC other than carboplatin-based regimens. For the prevention of CINV associated with HEC (including AC) and carboplatin-based regimens, the triple combination of a 5-HT₃RA, a neurokinin-1 receptor antagonist (NK₁RA), and dexamethasone is advised, with addition of olanzapine to the triplet when occurrence of nausea associated with HEC and AC regimens is an issue. Similar recommendations have been issued by the National Comprehensive Cancer Network (NCCN) [12] and the American Society of Clinical Oncology (ASCO) [13] for CINV prophylaxis in the HEC and MEC settings. NK₁RA-based regimens are constituted of either aprepitant (oral), fosaprepitant (i.v.), or rolapitant (oral), in combination with 5-HT₃RA–dexamethasone, or the fixed-combination agent NEPA (oral), comprising the NK₁RA netupitant and the 5-HT₃RA palonosetron, combined with dexamethasone alone. Recently, additional

formulations of NK₁RA that increase the convenience of administration of antiemetics have been developed and approved in the U.S. in 2018, for example, i.v. NEPA (fixed combination of fosnetupitant and palonosetron) [14], aprepitant emulsion for injection [15], and rolapitant injectable emulsion [16, 17]; i.v. NEPA also recently received approval in Europe [18]. After the occurrence of anaphylaxis, anaphylactic shock, and hypersensitivity reactions in the clinic with rolapitant injectable emulsion, a safety warning was issued [19] that led to the suspension of its distribution [20]. The new i.v. formulations of NEPA and aprepitant have recently been incorporated in the NCCN antiemetic guidelines and are recommended for the HEC and MEC settings [12]. Moreover, i.v. NEPA is advised as an alternative to oral NEPA in the HEC, AC, and carboplatin settings by MASCC/ESMO [10, 11].

Prevention is the main goal of international antiemetic guidelines. Correct management of nausea and vomiting in the first chemotherapy cycle is critical because CINV occurrence during first administration of emetogenic chemotherapy is associated with increased CINV risk in subsequent cycles [21, 22]. Guideline-consistent usage of antiemetic regimens can effectively prevent vomiting and, to a lesser extent, nausea in most patients with cancer [23–25]. Conversely, nonadherence to antiemetic guidelines leads to suboptimal CINV control [25, 26]. However, several studies have reported low guideline adherence for patients receiving HEC and MEC both in Europe [25, 27, 28] and the U.S. [26]. Low adoption in the U.S. of the newly recommended NK₁RA–5-HT₃RA–dexamethasone triplet for patients receiving carboplatin-based regimens was also reported recently [29].

The present study aims to analyze the usage of NK₁RA-based regimens for the prevention of CINV associated with HEC, including AC chemotherapy, and carboplatin-based (any dose of carboplatin) regimens in five European countries: France, Germany, Italy, Spain, and the U.K.

MATERIALS AND METHODS

Study Design and Inclusion Criteria

The Global Oncology Monitor from Ipsos Healthcare constituted the source of data for the analysis. The data set contains real-world prescribing information for all types of tumors, retrieved from patients' clinical records.

Geographically representative physicians from five European countries (France, Germany, Italy, Spain, and the U.K.) were screened for the following inclusion criteria: being a consultant-level physician, being the primary decision-maker for treatment and having direct access to patient clinical records, and treating five or more cancer patients per month with anticancer drug therapy. Additionally, the following country-specific criteria were used to ensure balanced physician representation: in Germany, 35% and 65% of physicians with office- and hospital-based practices,

respectively, across all specialties; in France, 70% and 30% of physicians with public and private practice, respectively, across all specialties; for regional representation in Italy, 45%, 25%, and 30% of physicians from the north, center, and south regions; in Spain, 23%, 29%, 23%, and 25% of physicians from the north, center, middle, and south; and in U.K., 93% of physicians representing old cancer networks regions.

Physicians completed online clinical record forms on all patients seen in consultation during the month of the study, irrespective of the specific tumor type (as per their natural assignment of patients). Physicians were allowed to submit between 5 and 36 records per month. For extrapolation of chemotherapy treatment data, clinical record forms were collected each month.

**Figure 1.** Distribution of chemotherapeutic regimens analyzed for which neurokinin-1 receptor antagonist-based antiemetic prophylaxis is recommended (n = 489,049 treatments). Abbreviations: AC, anthracycline-cyclophosphamide; HEC, highly emetogenic chemotherapy.**Figure 2.** Use of NK₁RA-based antiemetic regimens in the acute phase of chemotherapy-induced nausea and vomiting (day 1) for prophylaxis of HEC and carboplatin-based therapy in the overall study population (n = 489,049). Abbreviations: AC, anthracycline-cyclophosphamide; HEC, highly emetogenic chemotherapy; NK₁RA, neurokinin-1 receptor antagonist.

Treatment-related data collected by physicians from patient charts between January and December 2018 were compiled. Chemotherapy treatment data were extrapolated on the basis of the total number of physicians in the five countries who treat their patients with chemotherapy, that is, “the doctor universe.” A chemotherapy treatment was defined as at least one dose of a cytotoxic anticancer drug. Rigorous projection methodology was performed, where each patient record was projected individually on the basis of the following factors: (a) physician’s specialty/practice type/workload of patients, to reflect correct proportions of treating physicians in the population; (b) number of weeks since the patient was last seen, to ensure that patients on continual therapy are correctly represented despite less frequent visits; (c) cycle length, to adjust for the likelihood of counting an individual patient’s record each month; (d) number of cycles administered/number of additional cycles planned, for the best estimate of how often each patient’s record can be counted within a year—this is the “duplication factor.” These projections were used to estimate the number of treatments in each emetogenic risk chemotherapy category. The analyses are based on the projected estimates for the prevalence of the total number of chemotherapy treatments classified as HEC-based (including AC)

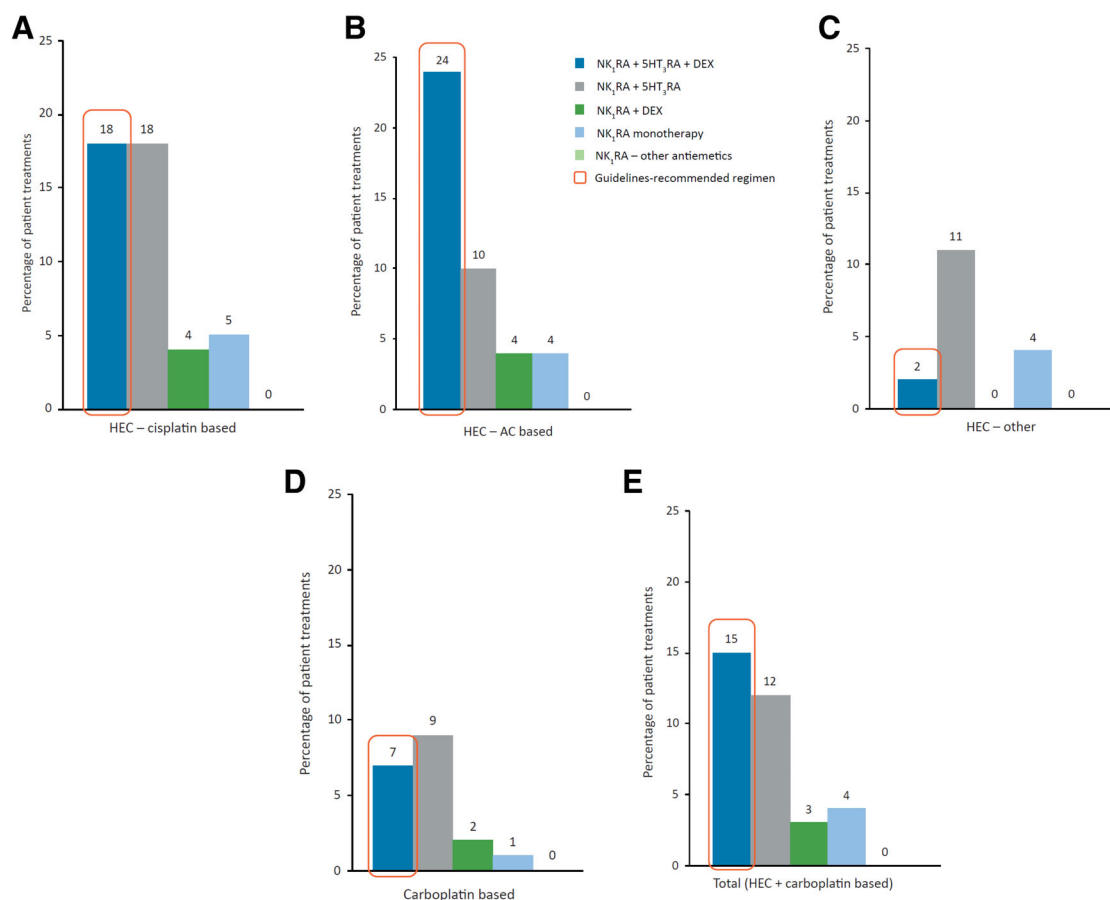

Figure 3. Distribution of NK₁RA-based antiemetic regimens used in the acute phase of chemotherapy-induced nausea and vomiting (day 1) for prophylaxis of cisplatin-based HEC (A), AC-based HEC (B), other HEC (C), carboplatin-based therapy (D), and any HEC and carboplatin-based therapy (E). Percentages of patients are reported to the overall study population ($n = 489,049$).

and carboplatin-based, that is, therapies requiring prophylaxis with NK₁RA-based regimens, per antiemetic guidelines. Data on prescribed antiemetic regimens for acute CINV prophylaxis are presented. Use of NK₁RAs only in the delayed phase is reported in the analysis by country.

Guideline adherence was calculated on the basis of the estimated number of all chemotherapy treatments for which NK₁RA-based antiemetic prophylaxis is recommended per MASCC/ESMO antiemetic guidelines, that is, HEC (including

cisplatin-based, AC-based, and other HEC) and carboplatin-based. Separate calculations were also performed for these individual chemotherapy types.

The emetic risk of chemotherapy was classified per MASCC/ESMO antiemetic guidelines, with AC combination being classified as HEC and carboplatin-based regimens (any dose of carboplatin) as "high" MEC [10, 11]. HEC treatments included cisplatin-based, AC-based, and "other HEC" therapies; among MEC treatments, only carboplatin-based

therapies were included. Guideline adherence was defined per the most current MASCC/ESMO antiemetic guideline recommendations, from 2016, at the time the survey was conducted [10].

Statistical Analysis

The data were analyzed using IBM SPSS Data Collection Survey Reporter, version 6.0.1 (SPSS, Hong Kong).

RESULTS

Study Participants and Study Population

Raw data were collected from a total of 610 physicians participating in the study: 154 from France, 111 from Germany, 176 from Italy, 68 from Spain, and 101 from the U.K. (Table 1). Most physicians were medical oncologists (54%), had a practice at an academic hospital (49%), and were located in urban areas (89%). Physicians completed a total of 45,324 clinical patient record forms for patients receiving chemotherapy. The most common cancer types were breast (23%), colorectal (18%), and non-small cell lung (10%) cancers. Among chemotherapy-treated patients, 27,417 received HEC or MEC.

After extrapolation of the data to the total number of registered physicians in these five countries, projected data represent a total of 1,394,848 chemotherapy treatments of any emetic risk (i.e., HEC, MEC, LEC, and minimally emetogenic chemotherapy, excluding hormonal-only therapy); of these, 882,310 correspond to HEC or MEC regimens. The analyses included 489,049 treatments for which NK₁RA-based antiemetic prophylaxis is recommended per MASCC/ESMO antiemetic guidelines, encompassing 326,607 HEC treatments (67%; cisplatin-based: 179,698 [37%]; AC-based: 125,203 [26%]; other HEC: 21,706 [4%]) and 162,442 carboplatin-based (33%) treatments (Fig. 1).

Use of NK₁RA-Based Antiemetic Regimens per Chemotherapy Setting

NK₁RA use was low across all guideline-recommended chemotherapy settings, with physicians prescribing NK₁RA-based prophylaxis for only 45%, 42%, 17%, and 19% of cisplatin-based, AC-based, other HEC, and carboplatin-based treatments, respectively (Fig. 2).

The guideline-recommended NK₁RA, 5-HT₃RA, and dexamethasone regimen for CINV prevention was given in only 18% of cisplatin-based, 24% of AC-based, and 2% of other HEC treatments, and in 7% of carboplatin-based regimens (Fig. 3A–D). Overall, the guideline-recommended NK₁RA-based triplet regimen was used in only 15% of HEC- and carboplatin-based treatments (Fig. 3E).

Among the 10 most frequent chemotherapeutic regimens for which NK₁RA-based prophylaxis was prescribed, cisplatin-based regimens (48%) were the most common, followed by AC-based regimens (39%) and carboplatin-based regimens (13%). Overall, the most common (>5%) chemotherapeutic treatments receiving NK₁RAs for the prevention of acute CINV were cyclophosphamide-epirubicin, cisplatin-gemcitabine, and cisplatin monotherapy, which

accounted for 12%, 7%, and 6%, respectively, of all NK₁RA-based antiemetic prescriptions (Fig. 4).

No Antiemetic Treatment

Overall, in 12% of all HEC and carboplatin-based treatments, no antiemetic prophylaxis was administered for the prevention of CINV, including 12% of cisplatin-, 4% of AC-, and 19% of carboplatin-based regimens (Fig. 2).

NK₁RA Use by Country

NK₁RA use was low across the five European countries, prescribed overall in only 45%, 42%, and 19% of cisplatin-, AC-, and carboplatin-based treatments, respectively (Fig. 5). In general, NK₁RA-based prophylaxis was higher in Germany and France than in Spain, the U.K., and Italy for all chemotherapy settings. For prophylaxis of cisplatin-based treatments, NK₁RA use was 61% in Germany and 54% in France and for AC combination regimens 69% and 58%, respectively. The use of NK₁RAs was lowest in the carboplatin setting for all countries, and especially in Italy, Spain, and the U.K., where the prescription rate was ≤10%. Remarkably, NK₁RAs were prescribed only in the delayed period in 1% of cisplatin-based therapies in Germany.

Physicians' Perception of the Emetogenic Risk of Chemotherapy

Only 55% of cisplatin-based treatments, 51% of AC-based treatments, and 24% of carboplatin-based treatments (classified as “high MEC” by MASCC/ESMO guidelines) were perceived as HEC by physicians (Fig. 6A).

From the perspective of physicians who prescribed NK₁RAs, 78% of cisplatin-, 74% of AC-, and 61% of carboplatin-based therapies were perceived as HEC (Fig. 6B). Conversely, among physicians who did not administer NK₁RA-based prophylaxis, the perceived emetogenic potential of these chemotherapies was lower, with only 35% of cisplatin-, 35% of AC-, and 15% of carboplatin-based treatments considered HEC.

DISCUSSION

This study showed that during 2018, adherence to 2016 MASCC/ESMO guideline recommendations for the prevention of acute CINV associated with HEC and carboplatin-based regimens was suboptimal in real-world clinical practice across five European countries. Noticeable is the reported low use of NK₁RAs in the HEC setting. Even though NK₁RAs were introduced in MASCC/ESMO guidelines in 2004 for CINV control following HEC and AC (considered MEC at the time) regimens [30], here we show that they were prescribed in only 45% of cisplatin- and in 42% of AC-based treatments during 2018 (Fig. 2). The reported NK₁RA use in the carboplatin setting was even lower, with only 19% of carboplatin-based treatments being associated with NK₁RA-based prophylaxis (Fig. 2). The limited use of NK₁RAs in this setting could reflect the shorter period for adoption of this recommendation since its incorporation in MASCC/ESMO guidelines in 2016 [10, 11]. Although NK₁RAs were mostly used for cisplatin-based regimens (both monotherapy and combinations), cyclophosphamide-epirubicin

was the most frequent chemotherapeutic regimen for which NK₁RA-based prophylaxis was prescribed (Fig. 4), which is consistent with breast cancer being the most common tumor type (23%; Table 1).

In addition to their consistently low use across HEC and MEC settings, NK₁RA-based regimens are largely not prescribed per MASCC/ESMO guidelines, that is, in combination with a 5-HT₃RA and dexamethasone. Specifically, the guideline-recommended NK₁RA–5-HT₃RA–dexamethasone triplet prophylaxis was prescribed in as few as 15% of all eligible treatments, including only 18% of cisplatin-, 24% of AC-, and 7% of carboplatin-based treatments (Fig. 3). Compared with a similar analysis performed in 2017 [31], the use of the triplet during 2018 remained the same in the cisplatin setting (18% vs. 18%), slightly increased in AC (20% vs. 24%), and slightly decreased for carboplatin-based regimens (11% vs. 7%).

Adherence to 2006 MASCC/ESMO guidelines was analyzed in a prospective observational study enrolling patients at various centers across Europe and showed a 55% adherence rate in the acute phase, with lowest adherence in the HEC (43%) and AC (32%) settings. Similar prospective and retrospective studies in Europe and the U.S. [26–28] as well as surveys of oncologists [32] and oncology nurses [33, 34] consistently showed low compliance with antiemetic guidelines.

Recently, and in line with our results, low guideline adherence during routine clinical practice was reported in a study analyzing patient data from five prospective non-interventional studies conducted between 2008 and 2015 to develop a tool to predict the risk of CINV [35, 36]. This study included a total of 1,198 patients receiving outpatient chemotherapy, of whom 27.4% and 52.8% received platinum- and anthracycline-based chemotherapy, respectively. Although these HEC regimens represent 80.2% of the total chemotherapy cycles analyzed, the guideline-recommended NK₁RA–5-HT₃RA–dexamethasone triplet was only prescribed in 12.2% of cycles and the olanzapine–NK₁RA–5-HT₃RA–dexamethasone quadruplet in 2.1%. Additionally, use of nonprescription antiemetic treatment was reported by 57.7% of all patients. A recent study in the U.S. using an electronic health record database reported low use of the NK₁RA–5-HT₃RA–dexamethasone triplet for prophylaxis of carboplatin area under the concentration-time curve (AUC) ≥ 4 mg/mL per minute regimens, reclassified as HEC by NCCN and ASCO guidelines since February and August 2017, respectively. The study analyzed antiemetic treatments prescribed for a total of 11,554 carboplatin courses from 2012 to 2018 [29] and showed only a mild increase in the use of the NK₁RA–5-HT₃RA–dexamethasone triplet from 16% in mid-2017 to 26% in the first quarter of 2018, which then dropped to 20% by the third quarter of 2018 [29]. In the two above-mentioned studies, inadequate prophylaxis was associated with high rates of nausea and vomiting [29, 35].

Remarkable is the high proportion of HEC and MEC treatments for which no associated antiemetic prophylaxis was prescribed (Fig. 2). This alarming result may be explained by physicians' underestimation of the emetic risk of chemotherapy and by their lack of awareness of antiemetic guidelines (despite being regularly downloaded from the societies' Web sites). Regarding physicians' perception of the risk for CINV, here we show that only 55% of cisplatin-, 51% of AC-, and

24% of carboplatin-based treatments were recognized as HEC by physicians (Fig. 6A). As expected, among physicians who prescribe NK₁RA-based regimens, the perceived emetic risk of chemotherapy correlated better with MASCC/ESMO guidelines' classification, with more than double the number of cisplatin- and AC-based treatments and more than four times the number of carboplatin-based treatments classed as HEC (Fig. 6B). Several studies have highlighted discrepancies between guideline-based emetic classification and physician- or oncology nurse-based emetic classification of chemotherapy, and a tendency to underrate the occurrence of CINV associated with both MEC [37] and HEC [38, 39]. Underestimation of the emetic potential of chemotherapy was cited as the main reason for uncontrolled CINV in the acute phase by 43% of oncologists participating in a European survey [32]. A potential reason for the underrated CINV risk of chemotherapy by physicians is low awareness of the risk classification described in guidelines. Additionally, patients tend to underreport CINV occurrence [40–42] because they either consider nausea and vomiting a sign of their chemotherapy being effective [39], fear their chemotherapy dose may be adjusted, or forget it if a long time has elapsed between its occurrence and the next medical appointment [43].

Even when physicians' perception of the emetic risk of chemotherapy is considered, overall prescription patterns did not follow guideline recommendations. This suggests that a lack of familiarity with antiemetic guidelines is an important driver for nonadherence. For example, although nearly half of cisplatin- and AC- based therapies and 24% of carboplatin-based therapies were perceived as HEC, only 18%, 24%, and 7% of them received guideline-recommended NK₁RA-based triplet prophylaxis, respectively. In addition, although physicians considered the total of cisplatin-, AC-, and carboplatin-based treatments as HEC, MEC, or LEC—thus requiring antiemetics per guidelines—as many as 12% of these chemotherapies were associated with no antiemetic prophylaxis (Fig. 2). In the above-mentioned oncologists' survey [32], only approximately a third of European oncologists reported awareness of MASCC/ESMO guidelines. Low guideline awareness was also reported by oncology nurses in Europe [34] and the U.S. [33], with only 40% and 6%, respectively, noting familiarity with MASCC/ESMO guidelines. Similarly, low uptake of the NK₁RA–5-HT₃RA–dexamethasone triplet for prophylaxis of carboplatin AUC ≥ 4 -mg/mL per minute regimens in the U.S. may reflect low awareness of changes in guidelines [29].

NK₁RA use was consistently low across all five European countries (France, Germany, Italy, Spain, and the U.K.), with NK₁RAs prescribed most in Germany and France (Fig. 5). Distinct traits in prescription patterns are observed depending on the chemotherapy setting. Although NK₁RAs were most used overall for cisplatin-based prophylaxis, they were primarily prescribed in the AC setting in France, Germany, and Italy. Additionally, although their use was lowest in the carboplatin setting in all five countries, usage varied from 47% and 29% in Germany and France, respectively, to $\leq 10\%$ in Italy, Spain, and the U.K. These discrepancies may be explained by local guideline recommendations or country-specific reimbursement policies. In the U.K., no country-level recommendations have been issued by the National Institute for Health and Care Excellence for the management of CINV, and antiemetic usage

is determined locally by cancer networks and trusts, usually following MASCC/ESMO guidelines, which may account for the low usage of NK₁RAs.

A weakness of the study is that the total number of chemotherapy treatments analyzed are extrapolated from patient charts on the basis of the total number of physicians in the five European countries analyzed. Nevertheless, use of a large database of more than 45,000 patients provides robustness to the results presented here. Another limitation is that antiemetic prophylaxis was only analyzed for the acute phase following chemotherapy. Consistent with previous reports, lower rates of guideline adherence would be expected for the delayed phase [25, 28, 33, 34]. Analysis of patient records for delayed CINV prophylaxis would provide a more detailed picture of prescription patterns in the real world for the overall CINV risk period. Finally, patients receiving other MEC regimens besides carboplatin, such as oxaliplatin, who may be eligible for NK₁RA-based prophylaxis but for whom no clear consensus has been reached in guidelines, were excluded from the analysis.

This study underscores the need to implement novel strategies to improve adherence to antiemetic guidelines for patients receiving HEC and carboplatin-based regimens, with a special focus on increasing the use of NK₁RAs. “Physician preference” was identified as the key barrier for implementation of guideline-recommended prophylaxis by oncology nurses in the U.S. and Europe [33, 34], and changing that preference is often difficult. Increasing health care providers’ awareness of antiemetic guidelines through educational programs combined with lectures by “experts,” feedback on institutional prescription patterns [30], and information on patients’ CINV outcomes [44] have been shown to modify physicians’ behavior and improve adherence. Collaboration between the multidisciplinary team, including clinicians, nurses, and pharmacists, in the implementation of standardized antiemetics orders on the basis of chemotherapy type has been shown to improve adherence at the institutional level [45]. In addition, application of standardized physician order-entry systems developed at medical centers in routine practice may increase compliance.

Complex administration schedules have been reported to interfere with use of guideline-recommended antiemetics [32, 34]. Some contributing factors include nurse-patient miscommunication during the explanation of complex schedules, and the desire of some patients to reduce the pill burden, leading them to only take their medication once symptoms appear. NEPA is the only fixed combination of an NK₁RA and a 5-HT₃RA and has the simplest administration schedule, offering high convenience of administration for most patients. Simple administration schedules not only could facilitate adherence by physicians but also could prevent patients from making medication mistakes, a recurring problem during home administration in the delayed phase [32]. In line with this, a recent noninterventional study evaluating patient-reported outcomes during the use of NEPA in routine clinical practice showed similar antiemetic efficacy as in the controlled pivotal trials, suggesting high treatment compliance by patients under real-world conditions [46]. On the other hand, a recent phase IV study demonstrated lower antiemetic effectiveness of the aprepitant/fosaprepitant-palonosetron-

dexamethasone regimen in the real world as compared with the reported efficacy in randomized controlled trials [47, 48]. Reduced patient compliance with the more complex aprepitant-based regimen in the real-world setting may account for this difference, at least in part.

Approaches to prevent patients from underreporting nausea and vomiting would provide physicians more realistic data about the incidence and severity of CINV and correct their perception of the emetic risk of chemotherapy. Use of electronic questionnaires, and phone- or Web-based applications for reporting of symptoms associated with chemotherapy have been shown to promote communication between patients and physicians during clinical visits [49–51]. Application of such tools in routine clinical practice may prove beneficial for appropriate reporting of nausea and vomiting by patients.

Besides improving adherence to antiemetic guidelines, correct patient assessment and management are needed at all stages of the cancer treatment pathway for optimal supportive care [52]. Uptake of supportive care guidelines is usually low, and most studies aim at increasing overall survival instead of focusing on improving symptom management. Recently, a study that evaluated remote patient monitoring through the electronic collection of chemotherapy-related symptoms in real time combined with timely feedback and medical intervention for symptom management demonstrated improved clinical outcomes, including overall survival [6]. There is a clear need for more studies that prospectively evaluate supportive care procedures and for the inclusion of patient-reported outcomes as endpoints in trials evaluating anticancer treatments, in order to ensure optimal patient care across the continuum of disease.

CONCLUSION

Our study results indicate low adherence to MASCC/ESMO antiemetic guidelines in real-world clinical practice in Europe. Only 15% of all HEC and carboplatin-based treatments for which NK₁RA-based prophylaxis is recommended received the guideline-compliant NK₁RA–5-HT₃RA–dexamethasone triplet. Of note, no antiemetic prophylaxis was prescribed for as many as 12% of the treatments. New strategies to improve guideline adherence, such as increasing awareness of guidelines, using simple and convenient antiemetic regimens, and preventing patients from underreporting CINV episodes, are urgently needed.

ACKNOWLEDGMENTS

Editorial and medical writing assistance was provided by Iratxe Abarrategui, Ph.D., C.M.P.P., and Oana Draghiciu, Ph.D., C.M.P.P., from Aptitude Health, The Hague, The Netherlands, funded by Helsinn Healthcare SA. The authors are fully responsible for all content and editorial decisions for this manuscript. Helsinn Healthcare SA subscribed to access Ipsos Healthcare. The nature of these syndicated, real-world data further validates the unbiased analysis of the current prescribing of supportive care in oncology. Partial results of this survey were presented at the European Society for Medical Oncology Annual Congress, October 19–23, 2018, Munich, Germany.
