OECD TRADE POLICY PAPERS

The OECD Trade Policy Paper series is designed to make available to a wide readership selected studies by OECD staff or by outside consultants. This series continues that originally entitled OECD Trade Policy Working Papers.

This paper is published under the responsibility of the Secretary-General of the OECD. The opinions expressed and the arguments employed herein do not necessarily reflect the official views of OECD member countries.

The publication of this document has been authorised by Ken Ash, Director of the Trade and Agriculture Directorate

This document and any map included herein are without prejudice to the status of or sovereignty over any territory, to the delimitation of international frontiers and boundaries and to the name of any territory, city or area.

This document has been declassified on the responsibility of the Working Party of the Trade Committee under the OECD reference number TAD/TC/WP(2014)9/FINAL.

Comments on the series are welcome and should be sent to tad.contact@oecd.org.

Abstract

EXPORTS AND EMPLOYMENT IN CHINA, INDONESIA, JAPAN AND KOREA

This paper examines the effects of exports on employment in China, Indonesia, Japan and Korea. It draws on input-output data for the period from 1995 to 2009 to estimate the effects on each industry's employment (i.e. direct effects) and on other industries' employment through intra-industry linkages (i.e. indirect effects). There are four major findings. First, at the aggregate level, the implied employment from exports increased in China, Japan and Korea. Second, at the industry level, exports and the shares of implied employment from exports increased in machinery-related industries such as Machinery (NEC), Electrical and Optical Equipment, and Transport Equipment in China, Indonesia and Korea. Third, although more than 80% of exports in the four study countries are from manufacturing industries, the employment effects are not limited to manufacturing industries. A significant number of workers in non-manufacturing industries depend upon manufacturing exports through vertical inter-industry linkages. Non-manufacturing industries account for between 40% and 60% of the implied employment from exports. Finally, in 2009, the share of implied employment from Chinese final demand exceeded that from the US final demand in both Japan and Korea. An implication of the overall results is that even in cases where an industry is not particularly directly export-oriented, the industry may still be subject to potential effects – positive or negative – of changes in export demand.

Key words: Trade, exports, employment, intra-industry linkages

JEL Classification: F16 (Trade and labour market interactions)

ACKNOWLEDGEMENTS

The OECD-led **International Collaborative Initiative on Trade and Employment** (ICITE) brought together ten international organisations in an effort to deepen our understanding of the linkages between trade and jobs and to develop policy-relevant conclusions. ICITE mobilised resources world-wide in an extensive programme of research, dialogue and communications. Participating organisations included: ADB, AfDB, ECLAC, IADB, ILO, OAS, OECD, UNCTAD, World Bank and WTO. The ICITE project was implemented under the auspices of a team at OECD. Douglas Lippoldt was the project manager. Jacqueline Maher provided secretarial and administrative support. Clarisse Legendre provided statistical assistance. The team is based in the Development Division, headed by Trudy Witbreuk, and under the direction of Raed Safadi, OECD Deputy Director for Trade and Agriculture, and Ken Ash, OECD Director for Trade and Agriculture.

The OECD published a series of Trade Policy Papers drawing on ICITE research. The ICITE papers benefitted from comments and other support from ICITE partner organisations, the Working Party of the OECD Trade Committee and other national experts, participants at ICITE regional conferences held during 2011-14 in Africa, Asia and Latin America, and other parts of the OECD including the Directorate for Employment, Labour and Social Affairs. This paper was developed as an input to the ICITE project. The views expressed are those of the author and do not necessarily reflect those of the OECD, OECD member country governments or partners of the ICITE initiative.

Executive summary

In light of the importance of the relationship between exports and employment, this paper examines the effects of exports on employment in China, Indonesia, Japan and Korea. The paper draws on the World Input-Output Database (WIOD) for the period from 1995 to 2009, which enables us to estimate the effects of exports on each industry's employment (i.e. direct effects) and on other industries' employment through intra-industry linkages (i.e. indirect effects). It clarifies how employment in these four countries relates to exports and how the relationships changed over the period. The paper, prepared as part of the OECD's International Collaborative Initiative on Trade and Employment (ICITE), builds on the earlier ICITE country study of Japan's exports and employment (Kiyota, 2011).¹

There are four major findings. First, at the aggregate level, the implied employment from exports - employment created through both direct and indirect effects from exports - increased in China, Japan and Korea. Second, at the industry level, exports and the shares of implied employment from exports increased in machinery-related industries such as *Machinery (NEC)*, *Electrical and Optical Equipment*, and *Transport Equipment* in China, Indonesia and Korea. Although this result does not necessarily mean that direct competition between developed and developing countries is increasing over the period, it provides an indication that it may be worthwhile for firms in developed countries to explore whether to differentiate their products by upgrading quality or moving up the value chain. Third, although more than 80% of exports in the four study countries are from manufacturing industries, the effects of exports on employment are not limited to manufacturing industries. A significant number of workers in non-manufacturing industries depend upon manufacturing exports through vertical inter-industry linkages. Non-manufacturing industries account for between 40 and 60% of the implied employment from exports. Finally, in 2009, the share of implied employment from Chinese final demand exceeded that from the US final demand in both Japan and Korea. The results indicate that the effects of the final demand of China are outpacing those of Japan and the United States.

An implication of the overall results is that even in cases where an industry is not particularly directly export-oriented, the industry may still be subject to potential effects – positive or negative – of changes in export demand. An industry's export dependence will be large if downstream customers are highly export dependent. Producers need to be aware not only of the export dependence of their industry but also of the export dependence of their upstream producers and downstream customers in different industries. Even non-exporters can be significantly affected by external changes in demand through such intra-industry linkages. In identifying the potential risks of negative external shocks, it is important for policy makers to identify how much employment is created indirectly as well as directly by exports.

¹ This paper was prepared as part of the OECD ICITE project launched in 2010. It uses WIOD data in light of their annual availability and compatibility with the similar framework employed in the original ICITE country study of Japan's exports and employment (2011) available here: http://www.oecd-ilibrary.org/trade/trade-and-employment-in-japan_5kg3nh62jg0x-en. In 2013, the OECD and WTO subsequently released the Trade in Value Added (TiVA) database, which will provide a high-quality data source for this type of analysis going forward: <http://www.oecd.org/sti/ind/measuringtradeinvalue-addedanoecd-wtojointinitiative.htm>.

I. Introduction²

With the growth of exports in the world economy, the effect of exports on employment is one of the major concerns for business leaders and policy makers in many countries. This tendency is particularly true in East and Southeast Asian countries after the financial turbulence in 2008, whose effect was initially expected to be rather small but turned out to be quite large. Indeed, IMF (2009) pointed out that “The impact on the real economy through the trade channel has been severe and similar across Asia. The drop in global demand has been particularly focused on automobiles, electronics, and other consumer durable goods that are an integral part of the production structure across East Asia. As a result, exports and industrial production have plummeted” (IMF, 2009, p. 71).

In light of the importance of the relationship between exports and employment, this paper examines the effects of exports on employment in China, Indonesia, Japan and Korea. We focus on China, Japan and Korea for two reasons. First, participation in global value chains has increased notably in these three countries.³ Second, these countries are sometimes compared with each other due to their regional proximities and their similarities and differences in economic performances.⁴ For the purpose of comparative analysis, the paper also focuses on one of the emerging economies in this region: Indonesia. This enables us to compare countries in different income levels in the East and Southeast Asia.⁵

Our motivation comes from two strands of research. One is the literature on the effects of exports on employment, which utilises a national input-output (IO) table. For example, Feenstra and Hong (2010) asked how much employment is created by Chinese exports. Using Chinese IO tables from 1997 to 2005, they found that exports became increasingly important in stimulating employment in China. However, the same gains could be obtained from the growth in domestic demand. Similarly, Kiyota (2012) asked the same question in Japan, using Japanese IO data between 1975 and 2006. The study found that Japanese employment increased in export dependence over the period. Note that the demand for labour can be affected not only by an industry's own exports (i.e. direct effects) but also by the exports of other industries through intra-industry linkages (i.e. indirect effects). Kiyota (2012) found that the magnitude of the indirect effects exceeded those of the direct effects over almost the entire period. OECD (2013) analysis found relatively high employment-export dependencies in China, Japan and Korea (1995-2008) and high dependencies (though declining over the period) in Indonesia.

² This paper was prepared by Kozo Kiyota under a consultancy for the OECD. I wish to thank Bernard Kennedy and Douglas Lippoldt for the helpful comments. The views expressed are those of the author and do not necessarily represent those of the OECD, its Member countries or ICITE partner organisations.

³ “Comparing 2009 with 1995, GVC (global value chain) participation has increased in almost all G20 countries, and particularly in China, India, Japan and Korea” (OECD, WTO and UNCTAD, 2013, p. 8). For more on this issue, see the OECD-WTO TiVA data referenced in footnote 1 above and the OECD Inter-Country Input-Output (ICIO) Database, available here: <http://www.oecd.org/trade/input-outputtables.htm>.

⁴ For example, using industry-level data, Motohashi (2007) compared the productivity of industries across China, Japan, Korea, Chinese Taipei and the United States. Similarly, Fukao, Inui, Kabe and Liu (2008) compared the productivity of listed firms in Japan, Korea and China.

⁵ According to the World Bank (2013), in 2011, per-capita GDP is USD 6 091 for China, USD 46 720 for Japan, USD 22 590 for Korea, and USD 3 557 for Indonesia (current USD). While covering other countries may also be of interest, we choose Indonesia because of the regional importance of its economy and the availability of the requisite data.

A second strand in the literature examines vertical linkages and international trade using global IO tables.⁶ For example, a recent study by Timmer, Los, Stehrer and Vries (2013) estimated value added trade to measure the competitiveness of economies using the World Input-Output Database (WIOD) for the period from 1995 to 2009.⁷ They found that gross exports overestimate the competitiveness of the economies that rely heavily on imported intermediates. Moreover, this bias has increased over time. Similarly, Foster-McGregor and Stehrer (2013) utilized the WIOD for the period from 1995 to 2011, extending the focus on value-added imports. They considered the value added share from third countries embodied in imports of a country from direct trading partners in relation to total imports, which they call the share of multilateral foreign value added content of imports. They found that the share of multilateral foreign value added content of imports was smaller than that of exports. Besides, it tended to be more similar across countries, implying that the value added content from the bilateral (rather than multilateral) relations is still more important.

Both strands of research have made significant contributions to the literature. However, there is potential for further exploration of the effects of exports through international vertical linkages on employment (e.g. as shown by the recent assessment, OECD, 2013).⁸ The first line of the study in the literature lacks the perspectives of international comparison while the second line, until recently, paid less attention to the effects on employment. This paper thus attempts to integrate and extend these two strands of study, focusing on China, Indonesia, Japan and Korea. That is, we examine the effects of exports on employment, taking into account of inter-industry and inter-country vertical linkages.

In doing so, this paper utilises the global IO tables in the WIOD.⁹ The use of the WIOD has the following advantage. As we will discuss in detail in Section 2, the global IO table reports domestic and imported intermediate inputs separately, and reports the exports for the intermediate and for the final uses separately. Note that the increases in the intermediate inputs are ultimately attributable to the increases in the final demand. In other words, because the demand for intermediate inputs is not independently determined from the demand for final goods, it should be determined “endogenously” in some sense.

⁶ An alternative approach is to impute a global IO table from national IO tables, employing a proportionality assumption: the proportion of intermediate to final goods is the same for domestic supply and imported products. Such an approach is employed by Trefler and Zhu (2010) and Johnson and Noguera (2012). Puzzello (2012) found that countries' use of domestic factors is overstated with the introduction of this assumption although biases generated on exported and imported factor contents cancel each other out. A recent study by Koopman, Wang and Wei (2014) proposed an alternative approach not relying on the proportionality assumption. The use of the WIOD is another way to relax the proportionality assumption.

⁷ More recently, OECD-WTO's Trade in Value Added database provides a cutting edge tool for the exploration of these issues. It is available here: <http://www.oecd.org/sti/ind/measuringtradeinvalue-addedanoecd-wtojointinitiative.htm>.

⁸ In an earlier study, the World Trade Organization-Japan External Trade Organization (WTO-JETRO) (2011, Chapter 6) examined the relationship between exports and employment using global IO tables. That study considered effects of exports on employment in East and Southeast Asian countries as well as the United States, using the Asian International IO table in 2000 and 2005 developed by the Institute of Development Economics (IDE)-JETRO. Although their motivation is the same as ours, the analysis is less formal in the sense that the study did not provide detailed explanations about the methodology and the analysis is based on preliminary data. Moreover, as we will discuss in detail in Section 2, the data used in our analysis have some advantages.

⁹ The OECD-WTO Trade in Value Added database can also be utilised for this type of analysis.

Previous studies such as Feenstra and Hong (2010) and Kiyota (2012) could not distinguish the difference between exports for the intermediate use and those for the final use. As Kimura (2006, p. 330) pointed out, “Active back-and-forth transactions of machinery parts and components are observed among countries with different income levels.” Besides, such transactions are expanding from East Asia to North America. For example, parts and components are first exported from Japan to China for processing, and then exported to Mexico for assembling, and then exported to the United States for the final use. The global IO table enables us to focus on the exports for the final use.¹⁰

Before starting, some terminological matters need to be clarified. First, following Feenstra and Hong (2010), we call employment created through both direct and indirect effects “implied employment”. Second, this paper focuses on exports for final use. In other words, the effects of exports mean the effects of exports for final use because the exports of intermediate inputs are “endogenously” determined as we will explain in Section 2. We also explain the data used in this paper in Section 2. Section 3 examines the effects of exports on employment. Section 4 investigates the effects of the final demand of China, Japan and the United States. A summary and concluding remarks are contained in Section 5.

2. Methodology and Data

2.1. Methodology

A logical starting point to estimate the implied employment from exports is to use the IO tables to examine both direct and indirect demand for labour.¹¹ This section provides the mathematical exposition of the methodology which follows a standard approach of a global IO analysis such as Timmer, Los, Stehrer and Vries (2013).

Suppose that there are M production factors and S industries in N countries. Although we will apply annual data in our empirical analysis below, time subscripts are left out for ease of exposition. Output in each country-industry is produced using domestic production factors and intermediate inputs, which are sourced domestically or from abroad. Output is used to satisfy final demand (either at home or abroad) or used as an intermediate input in production (either at home or abroad as well).

To trace the transactions of intermediate and final goods, it is necessary to define source and destination country-industries.¹² For a particular good, let i be the source country, j be the destination country, s be the source industry, and t be the destination industry. Let $y_i(s)$ be the value of output in industry s of country i , $f_{ij}(s)$ be the value of output exported from industry s in country i for the final use in any country j , $x_{ij}(s, t)$ be the value of output exported from industry s in country i to the intermediate use by industry t in country j . If $j = i$ ($j \neq i$), goods are used at home (abroad). The goods market clearing condition is written as:

$$y_i(s) = \sum_j \sum_t x_{ij}(s, t) + \sum_j f_{ij}(s). \quad (1)$$

¹⁰ For example, using detailed trade data for the period from 1991 to 2011, Ando and Kimura (2012) found that “transactions of Mexico with East Asia become much more active with a greater variety of product-country pairs and that the extent and depth of fragmentation of production in the US-Mexico nexus enhanced with a connection of East Asia particularly in the electric machinery sector” (p. 25).

¹¹ Note that the standard IO model is based on a number of restrictive assumptions such as constant returns to scale, and fixed input and labour coefficients. For more detailed discussion of some of the criticisms, see Baldwin (1994). OECD (1992) summarizes the advantages and limitations of the IO analysis in a comprehensive way.

¹² In this study, goods, products and industries are regarded as interchangeable.

For illustrative purposes, Figure 1 presents the structure of the global IO for a three-countries case (i.e. $N = 3$) where $v_j(t)$ indicates the value added of industry t in country j . As Figure 1 shows, the global IO reports domestic and imported intermediate inputs separately (from top to bottom), and reports the exports for the intermediate use and for the final use (from left to right). For example, Country 1's outputs go to the intermediate use for domestic industries ($x_{11}(s, t)$) and the intermediate use by Country 2 ($x_{12}(s, t)$) and by Country 3 ($x_{13}(s, t)$). Country 1's outputs also go to the final use in domestic market ($f_{11}(s)$) and the final use by Country 2 ($f_{12}(s)$) and by Country 3 ($f_{13}(s)$). Similarly, the imports (for final use) of Country 1 are captured by $f_{21}(s)$ and $f_{31}(s)$.

Let \mathbf{y} be the vector of production of dimension $(SN \times 1)$, which is obtained by stacking output levels $y_i(s)$ in each country-industry. Define \mathbf{f} as the vector of dimension $(SN \times 1)$ that is constructed by stacking world final demand for output from each country-industry $f_i(s) \equiv \sum_j f_{ij}(s)$. Let \mathbf{A} be a global intermediate input coefficients matrix of dimension $(SN \times SN)$ whose element $a_{ij}(s, t) \equiv x_{ij}(s, t)/y_j(t)$. This element indicates the output from industry s in country i used as the intermediate input by industry t in country j as the share of output in the latter industry. Therefore, the matrix \mathbf{A} describes how the goods of each country-industry are produced using a combination of domestic and foreign intermediate inputs.

Figure 1. Three-Country Global Input-Output Table

		Country 1	Country 2	Country 3	Country 1	Country 2	Country 3	Total
		Intermediate	Intermediate	Intermediate	Final demand	Final demand	Final demand	
		Industry	Industry	Industry				
Country 1	Industry	$x_{11}(s, t)$	$x_{12}(s, t)$	$x_{13}(s, t)$	$f_{11}(s)$	$f_{12}(s)$	$f_{13}(s)$	$y_1(s)$
Country 2	Industry	$x_{21}(s, t)$	$x_{22}(s, t)$	$x_{23}(s, t)$	$f_{21}(s)$	$f_{22}(s)$	$f_{23}(s)$	$y_2(s)$
Country 3	Industry	$x_{31}(s, t)$	$x_{32}(s, t)$	$x_{33}(s, t)$	$f_{31}(s)$	$f_{32}(s)$	$f_{33}(s)$	$y_3(s)$
Value added		$v_1(t)$	$v_2(t)$	$v_3(t)$				
		$y_1(t)$	$y_2(t)$	$y_3(t)$				

Note: $y_i(s)$ is the value of output in industry s of country i ; $f_{ij}(s)$ is the value of output exported from industry s in country i for final use in any country j ; $x_{ij}(s, t)$ is the value of output exported from industry s in country i for intermediate use by industry t in country j ; $v_j(t)$ indicates the value added of industry t in country j . For more detail about the notations, see the main text.

Equation (1) is rewritten as $\mathbf{y} = \mathbf{A}\mathbf{y} + \mathbf{f}$. Rearranging this, the following fundamental IO identity is obtained:

$$\mathbf{y} = (\mathbf{I} - \mathbf{A})^{-1}\mathbf{f}, \quad (2)$$

where \mathbf{I} is an identity matrix of dimension $(SN \times SN)$ and $(\mathbf{I} - \mathbf{A})^{-1}$ is so-called Leontief inverse (Leontief, 1936) whose element in row s and column t of this matrix means the total production value of industry s needed for production of one unit of final output in industry t .¹³

There are two remarks in this equation. First, in the IO analysis, final demand sectors \mathbf{f} are called exogenous sectors while intermediate input sectors are called endogenous sectors. All the changes in the endogenous sectors of an IO table are the results of changes in the exogenous sectors. Note that, in a global IO table, the exports of intermediate inputs are captured in the endogenous sectors. In this sense, therefore, the exports of intermediate inputs are determined endogenously in the global IO analysis. Second, in this connection, noting that $(\mathbf{I} - \mathbf{A})^{-1}$ is the

¹³ Value added trade can be, for example, captured by $\mathbf{v}(\mathbf{I} - \mathbf{A})^{-1}\mathbf{t}$, where \mathbf{v} is the vector of value added share and \mathbf{t} is the vector of net trade. For more detail, see Foster-McGregor and Stehrer (2013).

Leontief inverse of the intermediate inputs transactions between industries across countries, Equation (2) captures all the direct and indirect effects through the domestic vertical linkages between industries within a country (i.e. $j = i$) and the international vertical linkages between countries (i.e. $j \neq i$).

Let $L_i(s)$ be the number of workers working for industry s in country i and $l_i(s)$ be its labour-input coefficient: $l_i(s) \equiv L_i(s)/y_i(s)$. Denote \mathbf{l} as a vector of dimension $(SN \times 1)$ whose element is $L_i(s)$ and $\hat{\mathbf{L}}$ as a diagonal matrix of dimension $(SN \times SN)$ whose element is $l_i(s)$. From Equation (2), the effects of final demand on employment can be rewritten as:

$$\mathbf{l} = \hat{\mathbf{L}}\mathbf{y} = \hat{\mathbf{L}}(\mathbf{I} - \mathbf{A})^{-1}\mathbf{f}. \quad (3)$$

Equation (3) is used to estimate the effects of employment.

2.2. Data

This paper utilises WIOD data for the period from 1995 to 2009 (Timmer, 2012).¹⁴ The WIOD is built on national accounts data which were developed within the 7th Framework Programme of the European Commission.¹⁵ The WIOD provides time-series of global IO tables for 27 EU countries, 13 other major countries, and the rest-of-the-world (ROW). The 13 countries include non-EU OECD member countries such as Japan and the United States and emerging economies such as China, Indonesia and Mexico.¹⁶ These tables are constructed on the basis of officially published IO tables in conjunction with national accounts and international trade statistics.

The simplified structure of the world IO table is presented in Figure 2, which is the same structure as that of Figure 1. As Figure 2 shows, the WIOD reports domestic and imported intermediate inputs separately, and reports exports for intermediate use and final use. For

¹⁴ Going forward, the OECD-WTO Trade in Value Added (TiVA) database will provide a high-quality data source for this type of analysis: <http://www.oecd.org/sti/ind/measuringtradeinvalue-addedanoecd-wtojointinitiative.htm>. The next release is scheduled for November 2014 and will cover 61 economies and 34 industries.

¹⁵ The WIOD and all satellite accounts are available at <http://www.wiod.org>. The satellite accounts include National IO Tables, Socio Economic Accounts (i.e. data on employment, capital stocks, etc.), and Environmental Accounts. In this paper, we utilize World IO Tables released in April 2012 and Social Economic Accounts data released in February 2012. For a detailed description of the database construction, see Timmer (2012).

¹⁶ The list of countries in the WIOD is as follows. European Union: Austria, Belgium, Bulgaria, Cyprus^{1,2}, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxemburg, Malta, the Netherlands, Poland, Portugal, Romania, Slovak Republic, Slovenia, Spain, Sweden and the United Kingdom; North America: Canada and the United States; Latin America: Brazil and Mexico; Asia and Pacific: China, India, Japan, South Korea, Australia, Chinese Taipei, Turkey, Indonesia and Russia. The regional classification follows Timmer (2012, Table 1).

1. Note by Turkey: The information in this document with reference to “Cyprus” relates to the southern part of the Island. There is no single authority representing both Turkish and Greek Cypriot people on the Island. Turkey recognises the Turkish Republic of Northern Cyprus (TRNC). Until a lasting and equitable solution is found within the context of the United Nations, Turkey shall preserve its position concerning the “Cyprus issue”.
2. Note by all the European Union Member States of the OECD and the European Union: The Republic of Cyprus is recognised by all members of the United Nations with the exception of Turkey. The information in this document relates to the area under the effective control of the Government of the Republic of Cyprus.

example, Country 1's exports consist of exports for intermediate use by Country 2 and by the ROW and exports for final use by Country 2 and by the ROW. It thus enables us to focus on exports for final use. The database consists of 35 industries, of which 34 industries are listed in Tables 4-7 below plus the *Private Households with Employed Persons* industry. The values are available at current prices and at previous year prices.

Figure 2. Structure of World Input-Output Table: Two Countries and the Rest of the World

		Country 1	Country 2	ROW	Country 1	Country 2	ROW	Total
		Intermediate	Intermediate	Intermediate	Final demand	Final demand	Final demand	
		Industry	Industry	Industry				
Country 1	Industry	Intermediate use of domestic output	Intermediate use by Country 2 of exports from Country 1	Intermediate use by ROW of exports from Country 1	Final use of domestic output	Final use by Country 2 of exports from Country 1	Final use by ROW of exports from Country 1	Output in Country 1
Country 2	Industry	Intermediate use by Country 1 of exports from Country 2	Intermediate use of domestic output	Intermediate use by ROW of exports from Country 2	Final use by Country 1 of exports from Country 2	Final use of domestic output	Final use by ROW of exports from Country 2	Output in Country 2
Rest of the World (ROW)	Industry	Intermediate use by Country 1 of exports from ROW	Intermediate use by Country 2 of exports from ROW	Intermediate use of domestic output	Final use by Country 1 of exports from ROW	Final use by Country 2 of exports from ROW	Final use of domestic output	Output in ROW
Value added		Value added	Value added	Value added				
		Output in Country 1	Output in Country 2	Output in ROW				

Source: Timmer (2012, Figure 2).

An advantage of the use of the WIOD is that it provides Socio Economic Accounts which include annual data such as employment at the industry level.¹⁷ This enables us to examine the effects of exports on employment more precisely. Moreover, throughout the data collection effort, harmonisation procedures were applied to ensure international comparability of the data. This ensures data quality and enables us to conduct comparative analysis at the industry and national levels. A disadvantage is that, among 35 industries, the *Private Households with Employed Persons* industry does not necessarily report figures. If the entry is missing, we replace it with a zero. If input coefficients are not defined because of zero gross output, we also replace them with a zero.¹⁸

2.3. Descriptive statistics

Exports

Table 1 presents the evolution of gross exports in China, Indonesia, Japan and Korea from 1995 to 2009. There are four major findings with respect to export growth. First, China shows the remarkable export growth. Chinese exports were USD 734.6 billion in 2008, which was

¹⁷ A global IO table is also developed by the IDE-JETRO. Although the IDE-JETRO international IO table covers other Southeast Asian countries such as Thailand and is available from 1985, it is only available at five year intervals (year 2005 is the latest year). Its industry classification is less detailed (24-26 industries) than that of the WIOD and is not harmonised throughout the period. Consequently, this paper utilises WIOD. For more detail about the IDE-JETRO international IO table, see Meng, Zhang and Inomata (2013). As noted above, going forward the OECD-WTO Trade in Value Added (TiVA) database will provide a high-quality data source for this type of analysis

¹⁸ A problem with WIOD data is that there may be exports to the ROW that take negative values (e.g. *Mining and Quarrying* in Korea in 2009). This is because the exports to the ROW are defined as the residual of the total exports minus exports summed over the set of WIOD countries in the national supply and use tables. As for the negative values, we use them as they are stated. An advantage of the OECD-WTO TiVA database is that it excludes these outcomes unless they reflect changes introduced in the 2008 SNA and BPM6 related to merchanting transactions, where negative exports may still occur.

eight times as much as her exports in 1995 (USD 91.7 billion). Although Chinese exports declined from 2008 to 2009, the overall growth was the fastest among four countries. In 1995, Chinese exports were about half of Japanese exports (USD 186.8 billion). In 2009, however, Chinese exports became more than three times as much as Japanese exports (USD 206.2 billion).

Table 1. Evolution of Exports in China, Japan, Korea, and Indonesia

Source: WIOD, November 2013 Release.

Second, although Japanese exports grew by 50% from 1995 to 2008, the growth of Japanese exports was the slowest among the four countries. In addition, Japanese exports decreased by 34.3% between 2008 and 2009, which was the largest plunge among these countries. Third, Korean exports also grew rapidly over the period. Korean exports were USD 151.6 billion in 2008, which was 2.8 times as much as her exports in 1995. Although Korean exports fell by 13.6% from 2008 to 2009, Korean exports in 2009 were still 2.4 times as much as her exports in 1995.

Fourth, the growth of Indonesian exports was relatively modest in the sense that the growth rate was in between those of Japan and Korea. Indonesian exports in 2009 were USD 31.1 billion, which was about twice as much as her exports in 1995. Indonesian exports fell by 11.1% between 2008 and 2009, which was the smallest decline among these four countries.

The bottom panel of Table 1 reports the share of exports in total final demand. Three findings stand out from this part. First, the Chinese and Korean economies both show relatively high dependence on exports. In 2009, the export shares of China and Korea were 12.6% and 16.1%, respectively. In this connection, it is notable that Korean export dependence grew from 10.4% to 16.1% between 1995 and 2009. This table points to an increase in the potential vulnerability of Korean economy to negative demand shocks in other countries.

Second, in contrast, the Japanese economy shows relatively low dependence on exports. In 2009, the share of exports to total final demand was 4.2% in Japan, which was the smallest among these four countries. Nevertheless, considering the size of the Japanese economy, its growth was notable: from 3.6% in 1995 to 6.3% in 2007, before declining to 6.0% in 2008 and 4.2% in 2009. These figures imply an overall increase in the importance of exports in the Japanese economy. Finally, the Indonesian economy also shows relatively low export dependence. In 2009, the export share was 5.3%. Note that Indonesian exports increased by

75.8% from 1995 to 2009. The low export dependence thus suggests relatively high growth of the domestic final demand.

The fluctuations of export shares are relatively high in Indonesia and Korea. In Indonesia, the export share increased from 6.5% in 1995 to 14.7% in 1998, and then dropped to 10.2% in 1999. Similarly, in Korea, the export share increased from 10.4% in 1995 to 16.9% in 1998, and then declined to 14.6% in 1999. One possible reason for this is the Asian financial crisis during 1997-98. Despite the falls in Indonesian and Korean exports from 1997 to 1998, the shares of exports in domestic final demand increased in both countries. This means that domestic final demand shrunk more rapidly than exports during 1997-98, which coincides with the period of the Asian financial crisis. In other words, this result suggests that in this respect the Asian financial crisis hit Indonesia and Korea more severely than China and Japan.

Employment

Table 2 shows the evolution of employment, measured by the number of persons engaged in work. The major findings are twofold. First, employment growth was relatively modest in China, Indonesia and Korea. The growth of employment from 1995 to 2009 was 14.6% in China, 15.2% in Korea, and 24.0% in Indonesia. In these three countries, employment grew gradually throughout the period. Second, in contrast, the employment growth in Japan was negative for 1995-2009. Employment was almost constant between 1995 (53.8 million workers) and 2008 (53.5 million workers). From 2008 to 2009, however, employment fell by 8.1%. As a result, employment dropped to 49.3 million workers in 2009.

3. Effects of Exports on Employment

3.1. All industry

Table 3 presents the evolution of implied employment from exports in China, Indonesia, Japan and Korea, which is calculated using Equation (3).¹⁹ There are two notable findings in this table. First, for China and Korea, the implied employment from exports shows relatively large growth. From 1995 to 2009, the implied employment from exports grew by 28.5% in China and

¹⁹ These results differ from the estimates in OECD (2013), referenced above, which excluded data for the agricultural sector. Inclusion of agriculture in the assessment could result in some upward bias in implied employment estimates in cases where large numbers of workers in the sector are engaged in non-market activity or where there are significant productivity differentials among agricultural employers depending on their participation in global value chains. Hence, the Appendix attached below presents a robustness check of the employment results excluding agriculture.

34.7% in Korea. Accordingly, the share of implied employment from exports in total final demand increased from 9.1% to 10.2% in China, and 7.8% to 9.2% in Korea over the period. This result suggests the increasing relative importance of exports to domestic final demand in the Chinese and Korean economies.

Source: WIOD, November 2013 Release.

Second, in Japan and Indonesia, the implied employment from exports shows relatively high volatility. In Japan, the implied employment from exports grew from 3.4% to 4.9% between 1995 and 2007. However, it decreased to 3.5% in 2009. This result suggests that the Great Recession in 2008-09 hit the Japanese economy severely. In Indonesia, the implied employment from exports grew from 4.4% to 6.3% between 1995 and 1998 but decreased gradually to 4.1% in 2009. Noting that exports grew by 75.8% from 1995 to 2009 (Table 1) and the number of person engaged grew by 24.0% (Table 2), this result suggests that both the growth of domestic final demand and that of the labour force contributed to increased employment, which results in the fall in the share of implied employment from exports in Indonesia.

3.2. By industry

China

Table 4 presents the evolution of exports and implied employment from exports, by industry, in China. Notable findings are summarised as follows. First, the export growth of *Electrical and Optical Equipment* is remarkable. The share of exports grew from 21.1% to 39.3% between 1995 and 2009. Second, the export growth of *Machinery, Nec* and *Transport Equipment* is also notable. The shares of exports increased from 3.7% in 1995 to 9.2% in 2009 for *Machinery, Nec* and from 1.4% to 4.0% for *Transport Equipment*. Third, the share of *Agriculture, Hunting, Forestry and Fishing* is very small throughout the period.²⁰ It fell from 3.0% in 1995 to 1.0% in

²⁰

As noted above, concerns may arise that the agricultural sector in some developing countries appears to be somewhat heterogeneous in its employment composition, with a mix of market (relatively high productivity) and non-market (relatively low productivity) labour utilisation. Some indications of this can be found in the literature (e.g. Bowlus, and Sicular, 2003, p. 570; Wang, 2008, pp. 115-16). The Appendix (below) addresses this concern to check the robustness of our broad results for China.

2009. This implies that the agricultural products are consumed mainly in Chinese domestic market.

Table 4. Evolution of Exports and Implied Employment from Exports in China, by Industry

Source: WIOD, November 2013 Release.

Fourth, in contrast, the share of implied employment from exports in *Agriculture, Hunting, Forestry and Fishing* points remains relatively high, despite a decline from 45.9% in 1995 to 36.4% in 2009. This corresponds to the large share of *Agriculture, Hunting, Forestry and Fishing* in overall employment. In 2009, for example, the employment share of *Agriculture, Hunting, Forestry and Fishing* was 38.1% (Annex Table A5). In view of the high labour intensity of production in this industry including with respect to exports, even small changes in exports thus affect relatively large numbers of workers.²¹ In this connection, the export dependence of employment on non-manufacturing industries is also high in China. In 2009, about one-third of implied employment from exports is in non-manufacturing industries. This implies that manufacturing exports have significant effects on non-manufacturing as well as manufacturing employment through vertical inter-industry linkages.

Finally, on the one hand, the shares of implied employment from exports in *Machinery, Nec* and *Electrical and Optical Equipment* increased gradually. The combined shares of the implied employment from exports for these two industries increased from 4.7% to 8.2% during the period from 1995 to 2009. As exports increase, employment that depends upon exports also

²¹

The same argument can be applied to high volatility in the share of some of the services industries such as Chinese retail trade and Indonesian wholesale trade even though the aggregate non-manufacturing figures show relatively steady trends. The effects of the Asian financial crisis for 1997-98 and those of the Great Recession for 2008-09 may also contribute to the high volatility.

increased in these two industries. On the other hand, the implied employment from exports in *Textiles and Textile Products* and *Transport Equipment* is relatively stable. Between 1995 and 2009, the share changed from 9.6% to 10.2% in *Textiles and Textile Products* and from 0.5% to 0.8% in *Transport Equipment*. In these industries, changes in exports did not have significant effects on employment.

Indonesia

Table 5 presents the evolution of exports and shares of implied employment from exports, by industry, in Indonesia. There are three notable findings. First, the major exporting industries in Indonesia are *Food, Beverages and Tobacco*; *Textiles and Textile Products*; and *Leather, leather and Footwear*. These three industries accounted for 34.9% of exports in 2009, declining from 45.0% in 1995. It is also notable that the share of the implied employment from exports in *Textiles and Textile Products* increased from 9.2% to 16.0% during the period from 1995 to 2009.

Table 5. Evolution of Exports and Implied Employment from Exports in Indonesia, by Industry

	Exports (All industry = 100%)					Implied employment (All industry = 100%)

Note: Detailed annual figures are presented in Tables A2 and A10.

Source: WIOD, November 2013 Release.

Second, like China, the employment share of the implied employment from exports in *Agriculture, Hunting, Forestry and Fishing* was also large, although it fell from 40.4% to 25.2% between 1995 and 2009. Like China, the share of *Agriculture, Hunting, Forestry and Fishing* in implied employment from exports is still large.²² A small change in exports may thus affect relatively large numbers of workers.

²² As in the case of China, concerns may arise that the agricultural sector in Indonesia may be somewhat heterogeneous in its employment composition, with a mix of market (relatively high productivity) and

Finally, the export share of *Machinery, Nec* showed rapid increase from 3.0% in 1995 to 11.3% in 2009. In contrast, the implied employment from exports in *Machinery, Nec* increased slightly from 0.4% to 1.0% over the period. This result implies that the employment of *Machinery, Nec* is weakly associated exports during these years, possibly due to a rapid increase in productivity in this industry.

Japan

Table 6 presents the evolution of exports and shares of implied employment from exports, by industry, in Japan. Major findings are summarised as follows. First, Japan's major exporting industries include: *Machinery, Nec*; *Electrical and Optical Equipment*; and *Transport Equipment*. The combined export share of these three industries amounted to 73.4% in 2009. Between 1995 and 2009, the export shares of *Machinery, Nec* and *Electrical and Optical Equipment* decreased, while the share of *Transport Equipment* increased.

Table 6. Evolution of Exports and Implied Employment from Exports in Japan, by Industry

Note: Detailed annual figures are presented in Tables A3 and A11.

Source: WIOD, November 2013 Release.

Second, in this connection, the overall share of implied employment from exports in these three major industries remained relatively large despite a decrease from 44.6% in 1995 to 36.3% in 2009. In *Transport Equipment*, the share increased from 12.3% to 15.3% over the period while the shares of *Machinery, Nec* and *Electrical and Optical Equipment* declined. This result implies that there was structural change underway for these major exporting industries in Japan.

Finally, exports are also playing an important role for Japan's non-manufacturing industries. The share of implied employment from exports is relatively high in *Renting of Machinery and*

non-market (relatively low productivity) labour utilisation. Thus, the Appendix (below) addresses this concern to check the robustness of our broad results for Indonesia.

Equipment and Other Business Activities (10.4%), *Wholesale Trade* (8.8%), and *Hotels and Restaurant* (5.7%) in 2009. As a result, the share of implied employment from exports in non-manufacturing increased from 36.6% to 46.1% for 1995-2009. Noting that manufacturing exports accounted for 85.3% of the total in 2009, the result implies that a number of workers in non-manufacturing industries depend upon manufacturing exports through vertical inter-industry linkages.

Korea

Table 7 presents the evolution of exports and shares of implied employment from exports, by industry, in Korea. The major findings are threefold. First, the export share of *Textiles and Textile Products* fell significantly. Between 1995 and 2009, it dropped from 14.2% to 2.7%. Accordingly, the share of implied employment from exports in *Textiles and Textile Products* also decreased significantly from 13.6% to 2.6% over the period. This result suggests the decline in the relative importance of exports by *Textiles and Textile Products* in Korea.

Table 7. Evolution of Exports and Implied Employment from Exports in Korea, by Industry

	Exports (All industry = 100%)					Implied employment (All industry = 100%)				
	1995	2000	2005	2008	2009	1995	2000	2005	2008	2009

Note: Detailed annual figures are presented in Tables A4 and A12.

Source: WIOD, November 2013 Release.

Second, like Japan, major Korean export industries include *Machinery, Nec; Electrical and Optical Equipment*; and *Transport Equipment*. The share of these three industries amounted to 76.2% of exports in 2009. Between 1995 and 2009, the export shares of *Machinery, Nec; Electrical and Optical Equipment* increased slightly while that of *Transport Equipment* increased significantly from 23.5% to 39.5%. In a related manner, the share of implied employment from exports in these three industries increased from 27.4% to 30.8% between 1995 and 2009.

Finally, the exports also affected non-manufacturing industries in Korea. For example, the share of *Renting of M&Eq and Other Business Activities* increased from 3.4% in 1995 to 9.0%

in 2009. Similarly, the share of implied employment from exports in non-manufacturing increased from 43.4% to 53.5% between 1995 and 2009. Noting that the export share of manufacturing accounted for 89.5% in 2009, the result implies that the linkages through exports are expanding from manufacturing industries to non-manufacturing industries.

3.3. Discussion

At the aggregate level, the implied employment from exports increased in all four countries considered here. As a result, the dependence of employment on exports relative to domestic final demand gradually increased throughout the period for China, Japan and Korea. In Indonesia, however, the share of implied employment from exports was relatively flat. One possible reason for this is the rapid increase in domestic final demand and labour force. At the industry level, the shares of implied employment from exports increased in machinery-related industries such as *Machinery, Nec, Electrical and Optical Equipment*, and *Transport Equipment* in China, Indonesia and Korea, as the exports from these industries expanded. (In contrast, the overall share of implied employment from exports in these three industries decreased in Japan.) The result implies the increasing similarity of exports as well as labour contents across these countries.

This result is consistent with the findings of Schott (2008) and Kiyota (2010). Using US product-level import data, Schott (2008) found that China's export bundle similarity with the OECD (excluding the United States) was greater than one would expect given China's size and income level. Similarly, using Japanese product-level import data, Kiyota (2010) found that more than 85% and 83% of products exported from the US and the EU, respectively, to Japan are also commonly exported from China.

Note, however, that this result does not necessarily mean that direct competition between China and developed countries is increasing over the period. Both Schott (2008) and Kiyota (2010) found that the developed countries' exports were priced higher than China's export products with the implication that there is some differentiation in varieties. Nonetheless, Kiyota (2010) found that the price differences of developed countries' exports relative to China's exports were relatively small in some industries. The result implies that, for firms in developed countries, quality upgrading or moving up the value chains can be an important means of differentiating products.²³

Note also that, in Korea, the export share of *Textiles and Textile Products* declined significantly from 1995 to 2009. As a result, the implied employment from exports in *Textiles and Textile Products* also fell significantly over the period. In contrast, in Indonesia, the export share of *Textiles and Textile Products* decreased significantly from 1995 to 2009 but the share of the implied employment from exports in *Textiles and Textile Products* actually rose somewhat indicating increased export-related labour concentration in the sector. In Indonesia, therefore, a further negative shock on exports in *Textiles and Textile Products* may affect a relatively large number of workers.

Although more than 80% of exports are from manufacturing industries in all four of the countries, the effects of exports on employment are not limited to manufacturing industries. Non-manufacturing industries accounted for roughly 40 to 60% of the implied employment from exports. A significant number of workers in non-manufacturing industries depend upon manufacturing exports through vertical inter-industry linkages. This result implies that even where an industry is not particularly export-oriented in a direct manner, it may still be vulnerable to positive or negative demand changes with respect to exports. An industry's actual

²³ OECD (2008, p. 10) also argued the importance and policy implications of moving up the value chain.

export dependence will be large if downstream customers are highly export dependent. Producers need to be aware not only of the export dependence of their industry but also of the export dependence of their upstream producers and downstream customers in different industries. Even non-exporters can be significantly affected by external shocks through inter-industry linkages.

4. Effects of Final Demand: China versus the United States

While Section 3 focused on the overall exports, one may be concerned with the effects of foreign final demand. Are the effects of Chinese final demand on employment in Indonesia, Japan and Korea increasing? Are the effects of US final demand still larger than those of Chinese final demand? These questions are nontrivial because exports to China may simply be caused by the US final demand rather than the Chinese final demand. In identifying the potential risks from exports, it is worth examining the effects of foreign final demand. This section attempts to address this issue.

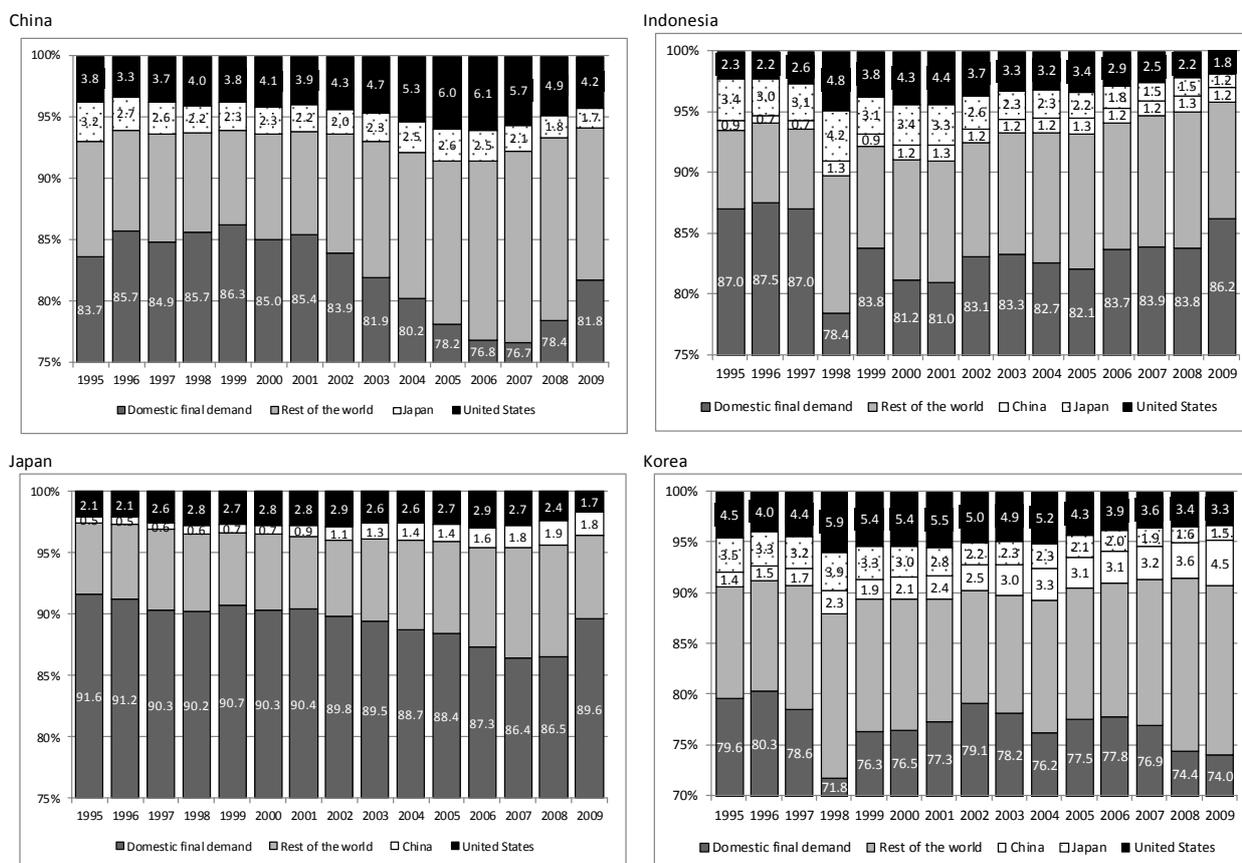

To answer these questions, we use Equation (3) but the analysis is slightly different from the analysis in Section 3. To see the difference between the analyses in Sections 3 and 4, let us go back to Figure 1. Without loss of generality, let us focus on Country 1. In Section 3, in examining the effects of exports on employment in Country 1, we focused on final use in Countries 2 and 3: $f_{12}(s) + f_{13}(s)$. In Section 4, in examining the effects of the final demand in Country 2 on employment in Country 1, we focus on the final use in Country 2: $f_{12}(s) + f_{22}(s) + f_{32}(s)$, which consists of Country 2's domestic demand $f_{22}(s)$ and the imports of Country 2 from Countries 1 and 3: $f_{12}(s) + f_{32}(s)$. The analysis of this section, for example, can capture the effects of exports (for final use) from China (e.g. Country 3) to the United States (e.g. Country 2) on Japanese employment (e.g. Country 1).²⁴

Figure 3 presents the results. We decompose the implied employment from final demand into that from domestic and foreign final demand. Foreign final demand consists of China, Japan, the United States and the ROW. The share of implied employment from each country's final demand in total final demand (= domestic + foreign final demand) is also presented.²⁵ Three messages stand out from this figure. First, in all four study countries, the domestic final demand plays an important role in creating employment. More than 70% of employment depends upon the domestic final demand in all countries and all years.

²⁴ It may also be interesting to examine the effects of Chinese exports to the United States on employment in Japan, Korea and Indonesia. However, as we will see below, the effects of the US final demand is less than 10%. We therefore focus on the overall US final demand, leaving the decomposition of imports to the reader.

²⁵ In this section, total final demand is the total final demand of each country to remove the effects of other countries' exports. In the previous section, the total final demand is measured as the total final demand of all countries.

Figure 3. Implied Employment from Final Demand, by Country
(Percentages)

Note: The percentages refer to the shares of implied total employment from domestic and foreign final demand. The scale on the vertical axis in each panel is truncated at 75%, except for Korea which is truncated at 70%. Total final demand is the total final demand of each country. Details of the decomposition are presented in Annex Table A13.

Source: WIOD, November 2013 Release.

Second, the shares of Japanese and US final demand are decreasing in China, Indonesia and Korea in recent years. In Korea, for example, the shares of Japanese and US final demand were 5.9% and 3.9%, respectively, in 1998, declining to 3.3% and 1.5%, respectively, in 2009. Similar patterns are observed in China and Indonesia. In contrast, the share of Chinese final demand is gradually increasing in Japan and Korea. In 1998, the share of Chinese final demand in Japan and Korea was 0.6% and 2.3%, respectively, increasing to 1.8% and 4.5%, respectively, in 2009. It is remarkable that the share of implied employment from Chinese final demand exceeded that from the US final demand in both Japan and Korea in 2009. These results together imply that the effects of the final demand of China are outpacing those of Japan and the United States.

5. Summary and Policy Implications

In light of the importance of the relationship between exports and employment, this paper examined the effects of exports on employment in China, Indonesia, Japan and Korea. This paper utilised the World Input-Output Database (WIOD) for the period from 1995 to 2009, which enables us to estimate the effects of exports on each industry's employment (i.e. direct effects) and on other industries' employment (i.e. indirect effects) through intra-industry

linkages. This paper clarifies how employment of the four study countries depends upon exports and how such dependences changed over the period.

There are four major findings. First, at the aggregate level, the implied employment from exports - employment created through both direct and indirect effects from exports - increased in China, Japan and Korea. In Indonesia, it is almost constant due to the rapid increases in domestic final demand. Second, at the industry level, the implied employment from exports increased in machinery-related industries such as *Machinery, Nec, Electrical and Optical Equipment*, and *Transport Equipment* in China, Indonesia and Korea, as the exports of these industries expanded. Although this result does not necessarily mean that direct competition between developed and developing countries is increasing over the period, provides an indication that may be important for firms in developed countries to differentiate their products via quality upgrading or by moving up the value chain.

Third, although more than 80% of exports are from manufacturing industries in these four countries, the effects of exports on employment are not limited to manufacturing industries. Non-manufacturing industries account for between 40 and 60% of the implied employment from exports. A significant number of workers in non-manufacturing industries depend upon manufacturing exports through vertical inter-industry linkages. Finally, in 2009, the share of implied employment from Chinese final demand exceeded that from the US final demand in both Japan and Korea. This result implies that the effects of the final demand of China are outpacing those of Japan and the United States.

An implication of the overall results is that even in cases where an industry is not particularly directly export-oriented, the industry may still be subject to potential effects – positive or negative – of changes in export demand. An industry's export dependence will be large if downstream customers are highly export dependent. Producers need to be aware not only of the export dependence of their industry but also of the export dependence of their upstream producers and downstream customers in different industries. Even non-exporters can be significantly affected by external changes in demand through such intra-industry linkages. In identifying the potential risks of negative external shocks, it is important for policy makers to identify how much employment is created indirectly as well as directly by exports.

In conclusion, there are several research issues for the future that are worth mentioning. First, although this paper focused on the number of workers, the labour inputs can also be adjusted to consider hours worked. Building on the approach of Kiyota (2011), an interesting next step would be to extend the analysis to examine the differences in labour market adjustment to trade shocks in terms of hours worked as well as numbers employed.²⁶ Second, the data used in this paper are valued at current prices. This means that the changes in input coefficients reflect changes in prices as well as the changes in technology. In order to extract the effects of the changes in technology, it would be necessary to utilise the data valued at constant prices. Finally, for a deeper understanding of the relationship between trade and employment, it may also be useful to examine not only the effects of exports but also those of imports. The studies by Groshen, Hobijin, and McConnell (2005) and De Backer and Yamano (2008) may be helpful for use in extending the present analysis. Some of these issues will be explored in the next stage of the author's research.

²⁶ It would also be useful to differentiate between exporting and non-exporting firms in order to better capture relative differences in the labour productivity of firms in a particular industrial sector. Work is underway at OECD to explore this issue as part of the improvements being developed for the TiVA database.

Appendix - Evolution of Implied Employment from Exports in China and Indonesia, by Industry: Robustness Check

The analysis of this paper assumes that all workers reported in the WIOD data engage in market activities with the same productivity. However, there may be a concern that the agricultural sector in developing countries appears to be somewhat heterogeneous in its employment composition, with a mix of market (relatively high productivity) and non-market (relatively low productivity) labour utilisation. Some indications of this can be found in the literature (e.g. Bowlus, and Sicular, 2003, p. 570; Wang, 2008, pp. 115-16).

The information on the difference between market and non-market labour utilisation is usually not available in the input-output (IO) data, including the WIOD data. In light of this heterogeneity, some studies utilising input-output analysis such as OECD (2013) have excluded such industries as agriculture and public administration to focus on market activities (which they called business sector). Following this approach, we employ another extreme assumption to check the robustness of our results: namely, that negligibly small number of workers in China and Indonesia engage in market activities in agriculture. Using an approach similar to that of OECD (2013), we thus re-estimate the implied employment from exports in China and Indonesia with the employment of the agricultural sector zeroed out.

Annex Table A14 presents the results for China and Indonesia, which corresponds to the implied employment from exports in Tables 4 and 5, respectively. Although the numbers did change significantly due to the exclusion of the substantial employment in agriculture (see Tables A5 and A6), the major messages of the paper remain unchanged. At the industry level, exports and the shares of implied employment from exports increased in machinery-related industries such as *Machinery (NEC)*, *Electrical and Optical Equipment*, and *Transport Equipment* in China and Indonesia. Moreover, although more than 80% of exports in these countries are from manufacturing industries, the effects of exports on employment are not limited to manufacturing industries. A significant number of workers in non-manufacturing industries depend upon manufacturing exports through vertical inter-industry linkages. The results together indicate that our results are relatively robust even when the analysis takes into account the non-market activities in the agricultural sector in China and Indonesia.
