## ABSTRACT

Various substituted dibenz[b,f][1,4]oxazepines underwent an enantioselective alkylation with Et<sub>2</sub>Zn catalyzed by a (R)-VAPOL-Zn(II) complex. The corresponding chiral 11-ethyl-10,11-dihydrodibenz[b,f][1,4]oxazepine derivatives were obtained with good yields and moderate enantioselectivities. This represents the first example of enantioselective addition of Et<sub>2</sub>Zn to cyclic aldimines.

## Introduction

Dibenzo[b,f][1,4]oxazepine derivatives are attractive compounds that recently have attracted huge attention from the pharmaceutical industry due to the wide spectrum of biological activities that present such compounds.<sup>1</sup> Among compounds containing the dibenzoxazepine scaffold are non-nucleoside HIV-1 reverse transcriptase inhibitors,<sup>2</sup> antidepressants,<sup>3</sup> analgesics,<sup>4</sup> anxiolytics<sup>5</sup> and a lachrymatory agent,<sup>6</sup> as well as a histamine H<sub>4</sub> receptor agonist,<sup>7</sup> PGE<sub>2</sub><sup>8</sup> and calcium<sup>9</sup> antagonists. In this context, 11-substituted-10,11-dihydrodibenz[b,f][1,4]oxazepine derivatives play an important role in medicinal chemistry and several derivatives have shown interesting biological activities (Fig. 1), therefore their synthesis are of great interest in organic synthetic chemistry.<sup>10</sup> However, catalytic asymmetric methodologies for the synthesis of this kind of compounds are scarce in the literature. So far, only iridium-catalyzed asymmetric hydrogenation of the corresponding seven-membered cyclic ketimines,<sup>11</sup> as well as enantioselective Mannich,<sup>12</sup> aza-Reformatsky,<sup>13</sup> alkynylation<sup>14</sup> and propargylation<sup>15</sup> reactions of the seven membered cyclic aldimines have been described. Therefore, the development of new methodologies to synthesize optically pure 11-substituted-10,11-dihydrodibenz[b,f][1,4]oxazepine derivatives is highly desirable for synthetic organic chemistry.

The catalytic asymmetric addition reactions of organometallic reagents to imines are a central processes in synthetic chemistry to prepare chiral amines,<sup>16</sup> which are important building blocks for pharmaceutical and medicinal chemistry.<sup>17</sup> In this context, the catalytic asymmetric addition of dialkylzinc reagents to imines is a convenient methodology to prepare chiral amines.<sup>18</sup> Several examples of the enantioselective addition of organozinc reagents to acyclic imines have been described in the literature.<sup>19</sup> However, the corresponding addition of dialkylzinc reagents to cyclic imines remains unexplored, to the best of our knowledge (Scheme 1). Hence, we present our results on the enantioselective addition of Et<sub>2</sub>Zn to dibenz[b,f][1,4]oxazepine derivatives, as a seven-membered cyclic imine, catalyzed by a (R)-VAPOL-Zn(II) complex in order to prepare chiral 11-ethyl-10,11-dihydrodibenz[b,f][1,4]oxazepine derivatives with good yields and moderate enantioselectivities.

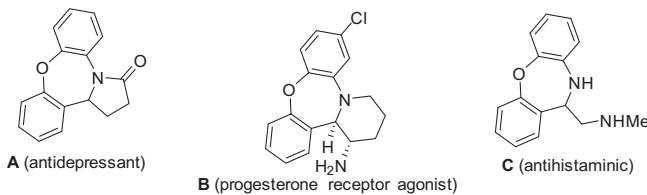

## Results and discussion

Optimization studies were performed with the alkylation reaction of seven-membered cyclic imine **1a**, as the model substrate, with Et<sub>2</sub>Zn in dichloromethane at room temperature. Several chiral Zn(II)-complexes, generated in situ from Et<sub>2</sub>Zn and chiral ligands **L** (Fig. 2), were tested and the results are summarized in Table 1.

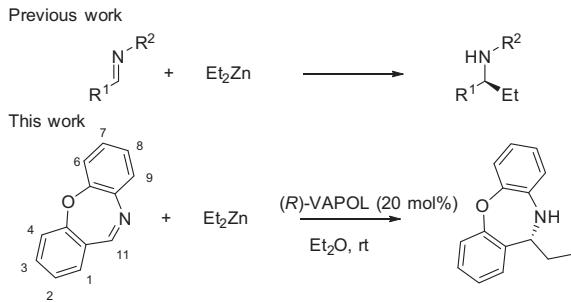

First, a family of BINOL ligands (**L1–L6**, entries 1–6 Table 1) were evaluated, and the corresponding amine **3a** was obtained, in general, with low yields and low enantioselectivities. Though, with (R)-6,6'-Br<sub>2</sub>-BINOL (**L2**) a promising 50% ee was observed.

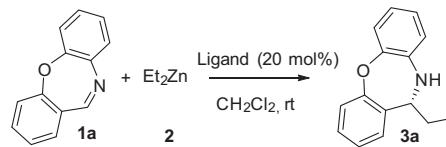

**Scheme 1.** Enantioselective addition of  $\text{Et}_2\text{Zn}$  to imines.

**Fig. 2.** Chiral ligands evaluated.

Then, we decided to examine vaulted ligands like (R)-VAPOL (**L7**) and (R)-VANOL (**L8**). The use of **L7** as a ligand (entry 7), afforded the product **3a** with better enantioselectivity (61% ee), although the yield was moderate (36%). When (R)-VANOL (**L8**) was used as a ligand (entry 8), **3a** was afforded in 40% yield, but almost as a racemic mixture. Subsequently, we decided to test different chiral aminoalcohols, such as quinine (**L9**) or diaryl prolinol ligands (**L10–L13**) used successfully in enantioselective zinc mediated reactions,<sup>13,20</sup> but the enantioselectivities observed were very low. Only Trost ligand<sup>21</sup> **L14** (entry 14) gave some asymmetric induction (20% ee). Other ligands such chiral  $\alpha$ -hydroxyamides **L15**

<sup>a</sup> Reaction conditions: **1a** (0.1 mmol), 1 M  $\text{Et}_2\text{Zn}$  (**2**) in hexane (0.5 mmol) and Ligand **L** (0.02 mmol) in 2 mL of  $\text{CH}_2\text{Cl}_2$  at room temperature for 24 h.

<sup>b</sup> Isolated yield after column chromatography.

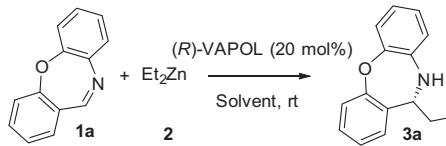

<sup>c</sup> Enantiomeric excess were determined by HPLC using chiral stationary phase.

<sup>d</sup> Opposite enantiomer was obtained.

(entry 15) and **L16** (entry 16), developed in our research group for the addition of organozinc reagents to carbonyl compounds<sup>22</sup> were also evaluated, but they proved to be unsuccessful ligands in the addition of  $\text{Et}_2\text{Zn}$  to cyclic imines.

With (R)-VAPOL (**L7**), which gave the best enantioselectivity, we decided to continue the optimization process testing different solvents (Table 2). Dichloroethane provided better conversion but lower enantioselectivity than dichloromethane. With ethereal solvents (THF, MTBE or  $i\text{Pr}_2\text{O}$ ) lower levels of enantioselectivity were obtained for compound **3a**. However, when  $\text{Et}_2\text{O}$  was used as a solvent an improvement in the enantioselective excess was observed and product **3a** was afforded in 69% ee (Entry 5, Table 2). Other solvents such toluene or  $\text{AcOEt}$  did not improve the results obtained with  $\text{Et}_2\text{O}$ . Our efforts to improve the enantioselective excess of compound **3a** were unsuccessful, therefore we decided to study

the scope of the reaction with the conditions shown in entry 6, Table 2.

We tested several cyclic seven membered imines containing different electron-withdrawing or electron-donating groups with Et<sub>2</sub>Zn (Scheme 2). The reaction, in general, proceed with good yields (40–71%) and moderate enantioselectivities (34–70% ee). When the substituents are placed in 7-position (**3b–3c**), the conversion and the enantiomeric excess observed were lower. Whilst, when the substituents were at 8-position the enantioselectivities were around 60%. On the other hand, the electronic character of the substituents at 2-position (**3g–3i**) had an influence in the enantioselectivity of the reaction. For example, electron-donating groups such methoxy led to the reaction product with 70% ee, whilst electron-withdrawing groups such chlorine lowered the enantioselectivity of the reaction (34% ee). Finally, naphthyls groups were tolerated in the reaction, obtaining the corresponding alkylated amines **3k** and **3l** with moderate enantioselectivities, 59% ee and 67% ee respectively. Our efforts to expand our methodology to other organozinc reagents were unsuccessful. When Me<sub>2</sub>Zn, Bu<sub>2</sub>Zn and iPr<sub>2</sub>Zn were tested under the optimized reaction conditions very low conversions to the corresponding alkylated products were observed.<sup>23</sup>

## Conclusions

In summary, we have reported the enantioselective alkylation of dibenzo[b,f][1,4]oxazepine derivatives with Et<sub>2</sub>Zn catalyzed by a (R)-VAPOL-Zn(II) complex. This methodology has provided an approach to synthesize optically active 11-ethyl-10,11-dihydrodibenzo[b,f][1,4]oxazepine derivatives with good yields (up to 76%) and moderate enantioselectivities (up to 70% ee). The present study extends the scope of the catalytic asymmetric addition of organometallic reagents to cyclic seven membered imines, and represents the first enantioselective addition of Et<sub>2</sub>Zn to cyclic imines.

23. We attribute these lack of reactivity for the other organozinc reagents ( $\text{Me}_2\text{Zn}$ ,  $\text{Bu}_2\text{Zn}$  and  $i\text{Pr}_2\text{Zn}$ ) due to the  $\text{Zn}(\text{II})$ -complex formed is different for each organozinc reagent, and the only reactive is the complex formed with  $\text{Et}_2\text{Zn}$ .
