ABSTRACT

A series of salicylaldehyde-2-pyridinehydrazone derivatives were found to exhibit interesting “turn-on” fluorescence response toward Zn^{2+} in water at neutral pH, which could be prepared readily from commercially available materials through a one-step reaction in ethanol at room temperature. Among these compounds, **1** showed a 22-fold fluorescence enhancement in 99% water/DMSO (v/v) at pH 7.0 with a linear range of 0.10–1.00 $\mu\text{mol/L}$ and detection limit of 30 nmol/L Zn^{2+} . Especially, **1** was not affected by Cd^{2+} which usually induced a comparable fluorescence response to that of Zn^{2+} in other reported works. Moreover, live cell imaging showed that **1** could be useful for monitoring Zn^{2+} within biological samples.

1. Introduction

The development of chemosensors for metal ions with high selectivity and sensitivity is an active field in analytical chemistry. Fluorescent chemosensors for metal ions have attracted particular attention due to their advantages such as low cost, simplicity, good sensitivity, capability of real-time detection and non-destructive emission signals [1–4]. Zinc is the second most abundant transition metal ion after iron in the human body, and is a very important ion species in many biological activities such as neural signal transmission, gene expression, cellular metabolism and DNA binding or recognition [5–8]. To date, numerous fluorescent chemosensors for Zn^{2+} have been developed using coumarin, rhodamine, fluorescein, BODIPY, etc. as fluorophores and using di-2-picolylamine, quinoline, bipyridine, etc. as receptors [9–12], which exhibited excellent selectivity and sensitivity toward Zn^{2+} and some of them could be used for biological imaging in a physiological environment. Recently, our group have also reported fluorescent chemosensors for Zn^{2+} based on salicylaldehyde Schiff-base [13,14]. Nevertheless, most of these reported chemosensors have some limitations. On one hand, the preparations of complicated fluorophores and receptors lead to multiple-step synthesis with high cost [15–23]; on the other hand, because of the poor water-solubility for most fluorescent sensors, high content of organic cosolvents are necessary to

exhibit satisfying analytical performances [13,14,17,24–31], which is not compatible for the detecting of Zn^{2+} in biologic system and practical samples. Moreover, many reported fluorescent chemosensors for Zn^{2+} encountered difficulty in distinguishing Zn^{2+} from Cd^{2+} , because Cd^{2+} is in the same group of the periodic table with Zn^{2+} and usually induces a comparable fluorescent response to that of Zn^{2+} [17,18,21,22,32–34]. Therefore, it is challenging to develop a facilely synthesized, sensitive and selective fluorescent chemosensor for Zn^{2+} that could be useful for monitoring Zn^{2+} in aqueous solutions and biological samples.

In this paper, salicylaldehyde-2-pyridinehydrazone-based “turn-on” fluorescent chemosensor **1** (3,5-dichloro-2-hydroxybenzaldehyde-2-pyridinehydrazone) and its control compounds for detecting Zn^{2+} in water at neutral pH were reported. Upon the addition of Zn^{2+} to an aqueous solution of **1** at neutral pH, enhancement of blue fluorescence emission was observed, enabling fluorescence “turn-on” detection of Zn^{2+} by naked-eye under illumination with a UV lamp (Fig. 1b). Especially, **1** is a Zn^{2+} -selective fluorescent chemosensor that is less affected by physiological relevant metal ions including Cd^{2+} , thus, live cell imaging of Zn^{2+} was successfully performed with **1**.

2. Experimental

2.1. Materials and methods

Unless otherwise noted, all the materials of analytical grade were used in the experiments without further purification.

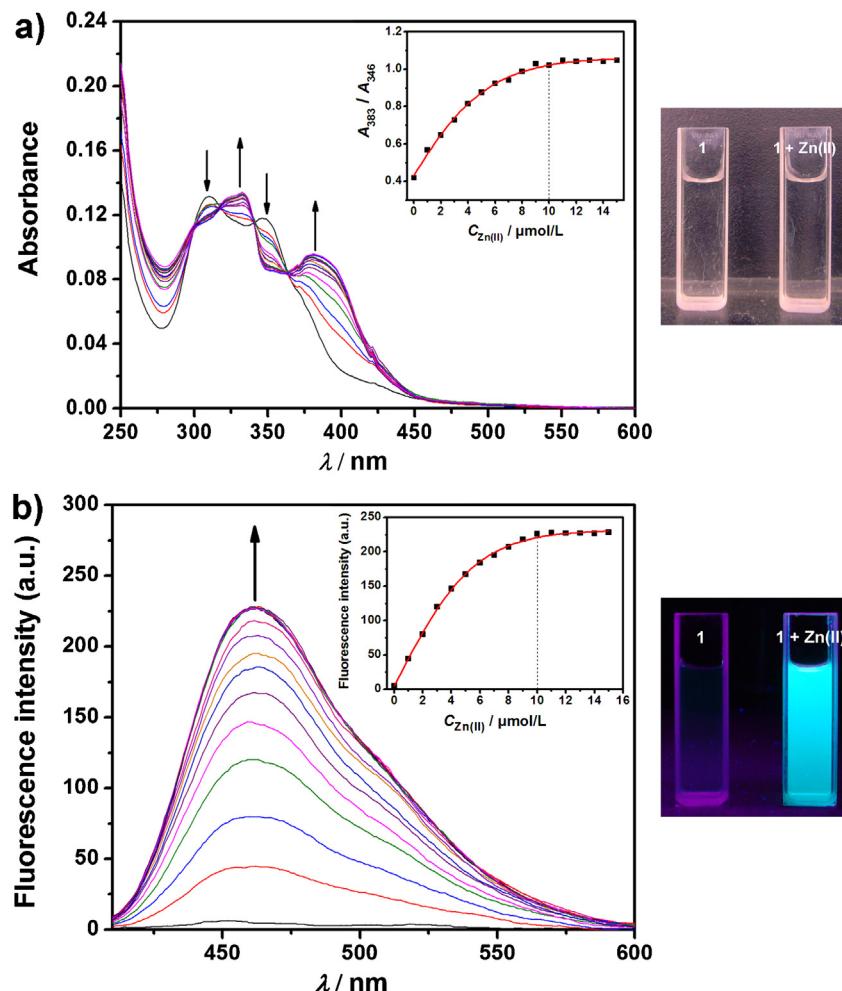

Fig. 1. (a) Absorption spectra of 10 μmol/L **1** upon the addition of 0–15 μmol/L Zn²⁺. Inset: The absorbance ratio (A_{383}/A_{346}) as a function of Zn²⁺ concentration. (b) Fluorescence spectra of 10 μmol/L **1** upon the addition of 0–15 μmol/L Zn²⁺. Inset: The fluorescence intensity at 460 nm as a function of Zn²⁺ concentration, excitation was at 364 nm. The photos on the right are **1** in the absence and presence of 1 equiv. Zn²⁺ in a glass cuvette excited by sun-light and UV light (365 nm). Conditions: [1] = 10 μmol/L, [Zn²⁺] = 10 μmol/L, 99% water/DMSO (v/v) at pH 7.0 buffered by 10 mmol/L Tris-HCl.

3,5-Dichloro-2-hydroxybenzaldehyde, 3,5-dichlorobenzaldehyde, phenylhydrazine, pyrithione, 4-fluoro-2-hydroxybenzaldehyde, 5-chloro-2-hydroxybenzaldehyde, 5-bromo-2-hydroxybenzaldehyde, 2-hydroxybenzaldehyde, 4-methoxy-2-hydroxybenzaldehyde, 4-diethylamino-2-hydroxybenzaldehyde, tris(hydroxymethyl)aminomethane were purchased from Alfa Aesar Co., Tianjing, China. 2-Hydrazinopyridine was purchased from J&K Chemical Co., Beijing, China. Unless otherwise noted, all the other materials were purchased from Sinopharm Chemical Reagent Beijing Co., Beijing, China. Doubly distilled deionized water was used throughout the experiments. The solutions of all metal ions were prepared from their nitrate salts. Tris-HCl buffer solutions with different pH were prepared using 10 mmol/L Tris and proper amount of HCl or NaOH under adjustment by a pH meter. Absorption spectra were carried on a JASCO V-550 UV-vis spectrophotometer equipped with an ETC-505 peltier thermostatted single cell holder, 5 cm quartz cells. Fluorescence spectra were recorded on a JASCO FP-6500 spectrofluorimeter equipped with an ETC-273T peltier thermostatted single cell holder, 1 cm quartz cells. All pH measurements were made with a pH-3C pH meter (Shanghai Precision & Scientific instrument Co., Ltd, Shanghai, China). ¹H and ¹³C NMR spectra were recorded using a JOEL JNM-ECA300 spectrometer operated at 300 MHz. ESI-MS spectra were carried on a HP 1100 LC-MS spectrometer without using the LC part. Elemental analyses were carried out on an Elementar vario

micro cube (Germany). Fluorescence imaging was observed under an Olympus FV-1000 confocal microscope.

2.2. Absorption and fluorescence measurements

Absorption and fluorescence titrations were recorded at 25 °C, performed by addition of small aliquots of **1** and different metal ion working solutions to buffer stock solution (10 mmol/L Tris-HCl of desired pH) in a quartz cell. After being well mixed, the solutions were allowed to stand at 25 °C for 2 min, and then absorption or fluorescence spectra were recorded. For the analysis of Zn²⁺ containing water samples, 0.030 mL of 1 mmol/L stock solution of **1** and 0.600 mL of buffer stock solution (50 mmol/L Tris-HCl of pH 7.0) were added to 2.370 mL sample solutions, and then well mixed for 2 min before test.

2.3. Preparation of cells

HeLa Cells were obtained from NIH, and reagents for culture were purchased from HyClone. HeLa cells were cultured in Dulbecco's modified Eagle medium (DMEM) supplemented with 10% fetal bovine serum, 1% penicillin and 1% streptomycin at 37 °C in a 5% CO₂ incubator. The cells were transferred to a glass-bottomed dish and incubated for 24 h before dye-loading.

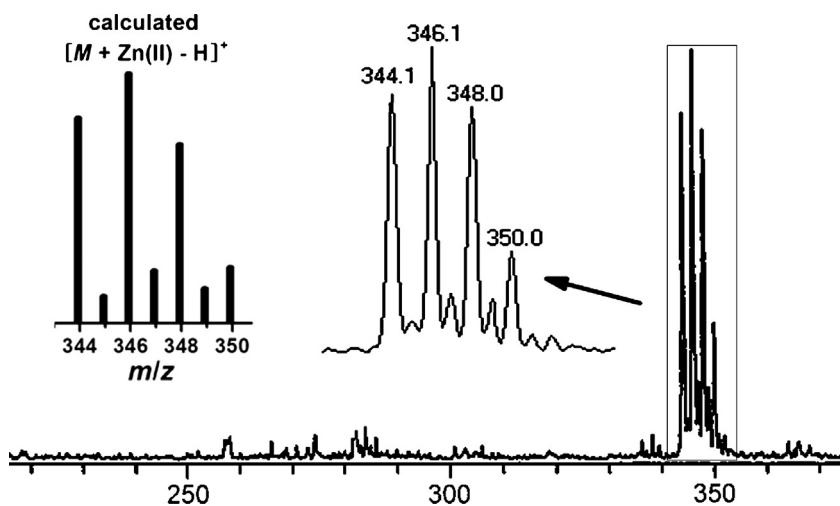

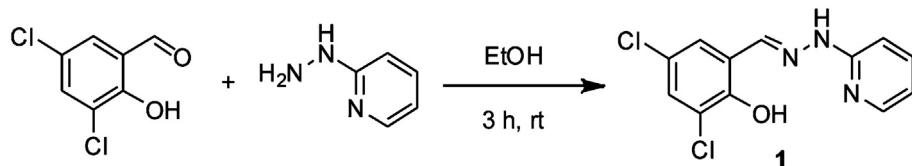

Fig. 2. ESI-MS spectrum of **1** in the presence of 2 equiv. Zn^{2+} . Inset: calculated isotopic patterns.

Scheme 1. Synthesis of **1**.

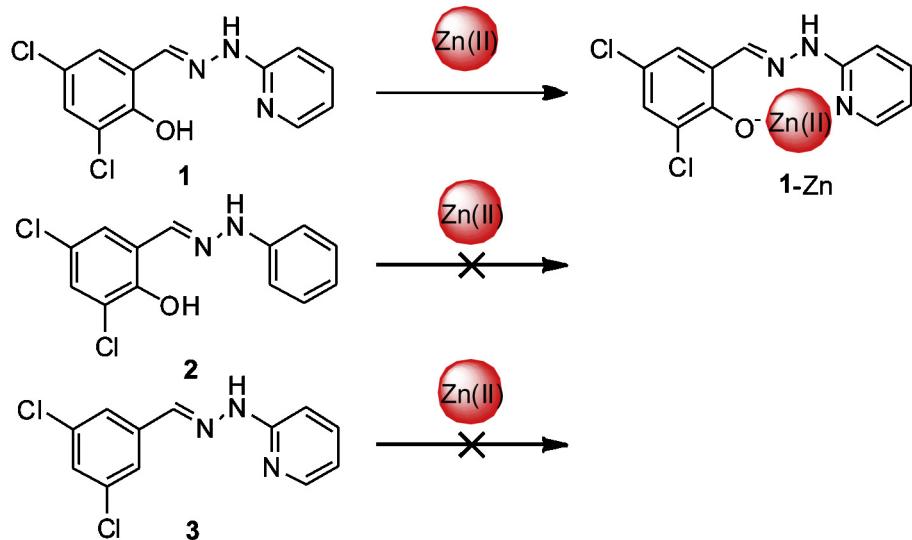

2.4. Synthesis of sensing molecules

General synthetic procedures of compounds **1–3** and **1a–f** are as follows. 1 mmol corresponding aldehyde (for **3**, 3,5-dichlorobenzaldehyde was used) and 1 mmol 2-hydrazinopyridine (for **2**, phenylhydrazine was used) were dissolved in 20 mL absolute ethanol. The mixture was stirred at room temperature for 3 h to form precipitate. The resulting precipitate was filtrated and washed with 20 mL of absolute ethanol three times. After being dried under reduced pressure, products were obtained in high yields (77–86%). The products were characterized by ESI-MS spectra, elemental analyses, 1H and ^{13}C NMR spectra (see Supporting Information).

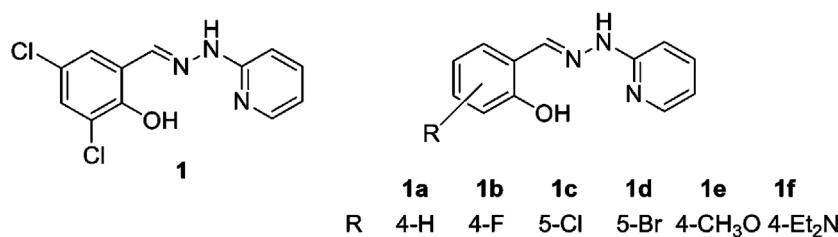

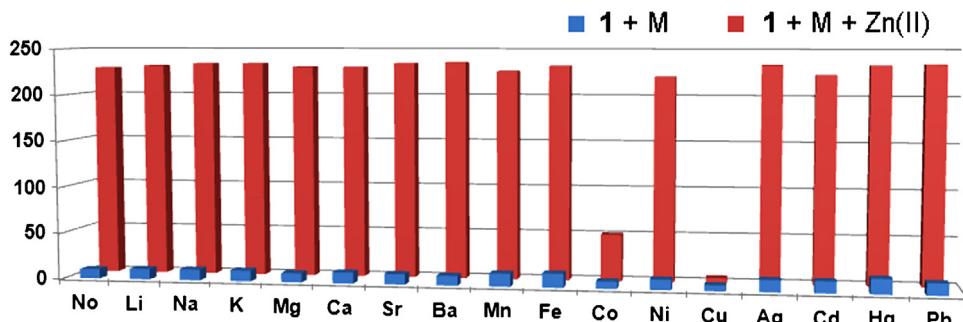

3. Results and discussion

3.1. Binding of **1** with Zn^{2+}

Absorption and fluorescence spectra were utilized for studying the binding mechanism of **1** with Zn^{2+} . Upon the addition of Zn^{2+} into 10 $\mu\text{mol}/\text{L}$ **1** in 99% water/DMSO (v/v) at pH 7.0 buffered by 10 mmol/L Tris-HCl, the absorption bands at 310 and 346 nm decreased gradually, new absorption bands at 333 and 383 nm emerged simultaneously. Four isobestic points could be found (Fig. 1a). In its fluorescence spectra under the same condition, more than 22-fold fluorescence enhancement at 460 nm occurred upon

Scheme 2. Proposed mechanism for the fluorescence change of **1** upon the addition of Zn^{2+} .

**Scheme 3.** Chemical structures of compounds **1** and **1a-f**.**Fig. 3.** Fluorescence intensity of 10 μmol/L **1** with 10 μmol/L different metal ions in the absence and presence of 10 μmol/L Zn²⁺. Ions: blank, Li⁺, Na⁺, K⁺, Mg²⁺, Ca²⁺, Sr²⁺, Ba²⁺, Mn²⁺, Fe³⁺, Co²⁺, Ni²⁺, Cu²⁺, Ag⁺, Cd²⁺, Hg²⁺, Pb²⁺. Conditions: 99% water/DMSO (v/v) at pH 7.0 buffered by 10 mmol/L Tris-HCl. Excitation and emission was at 364 and 460 nm, respectively.

the addition of Zn²⁺ (Fig. 1b). The nonlinear fitting of the titration curve revealed the binding of **1** and Zn²⁺ was most probably a 1:1 stoichiometry with an association constant K_a value about 5×10^4 L/mol. To study the metal-to-ligand ratio, Job's plot was established from the fluorescence spectra of **1** and Zn²⁺ with a total concentration of 10 μmol/L. As shown in Fig. S1, the result suggests the formation of a 1:1 complex. Moreover, the ESI-MS spectrum of **1**-Zn²⁺ supplied a more direct evidence for the 1:1 metal-to-ligand ratio: in the presence of 2 equiv. Zn²⁺, a clear peak at $m/z = 346.1$ ([M+Zn(II)-H]⁺, calcd 345.9) could be observed, and the isotopic patterns corresponded very well with the calculated ones (Fig. 2). Fluorescence emission enhancement and emission red shift from 452 to 460 nm of **1** upon binding with Zn²⁺ is considered to be due to the formation of **1**-Zn²⁺ complex: when complex formed the C=N isomerization [36,37] and excited-state proton transfer (ESPT) [34,38] are inhibited and chelation-enhanced fluorescence (CHEF) [24,35] was observed (Scheme 1).

Control compounds **2** and **3** were synthesized which lack pyridine and hydroxyl group compared with **1**, respectively (Scheme 2). Both of them showed no response to Zn²⁺ in absorption under the same condition as **1** (Figs. S2 and S3). Thus, the pyridine and hydroxyl group of **1** were both indispensable for its Zn²⁺ binding property.

1a-f were also synthesized as control compounds to understand the effect of substituent on 2-hydroxybenzaldehyde (Scheme 3). All of these compounds showed fluorescence "turn-on" response toward Zn²⁺ in water at neutral pH except for **1f**, which contains an electron-donating group of diethylamino. Among these compounds, **1** shows the longest wavelength emission and the largest fluorescence enhancement, and **1**-Zn²⁺ complex has the best fluorescence quantum yield (Table S1). Furthermore, both of 3,5-dichloro-2-hydroxybenzaldehyde and 2-hydrazinopyridine are commercially available reagents of low cost.

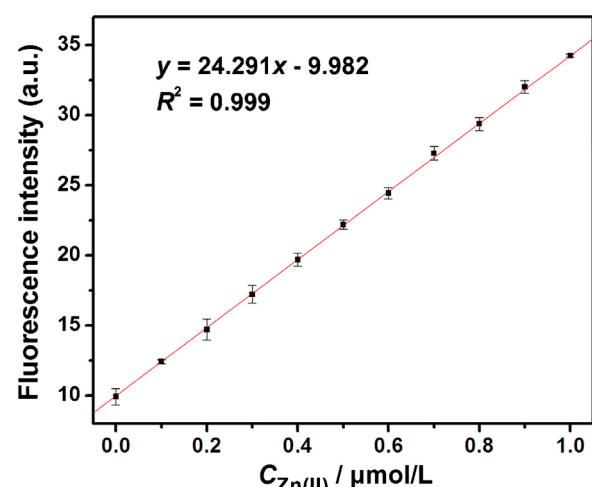

3.2. Selectivity of **1** to Zn²⁺ over other metal ions

The influences of other metal ions on the fluorescence spectra of **1** were investigated to study the selectivity of **1** to Zn²⁺. As shown in

Fig. 3, the response of **1** against those metal ions revealed a remarkable selectivity to Zn²⁺. Even in the presence of Cd²⁺, fluorescence enhancement was not detected. The high selectivity may be due to its specific binding affinity of **1** toward Zn²⁺ over Cd²⁺. Other competitive metal ions showed no interference except for Co²⁺ and Cu²⁺, which are paramagnetic metal ions leading to fluorescence quenching [4,39]. Although their quenching efficiency reached to 80% and 100%, respectively for Co²⁺ and Cu²⁺, their presence in biological samples is much less than Zn²⁺ and these interferences could be negligible when **1** is applied for such sample analysis.

3.3. Optimizing the pH for fluorescence determination of Zn²⁺

To investigate the pH effect, the fluorescence spectra of **1** in the presence of 1 equiv. Zn²⁺ were examined. As shown in Fig. S4, the fluorescence of **1**-Zn²⁺ complex reached to the maximum at pH

**Fig. 4.** Fluorescence intensity at 460 nm of **1** (10 μmol/L) as a function of Zn²⁺ concentration (0–1.00 μmol/L). Conditions: 99% water/DMSO (v/v) at pH 7.0 buffered by 10 mmol/L Tris-HCl. Excitation and emission was at 364 and 460 nm, respectively.

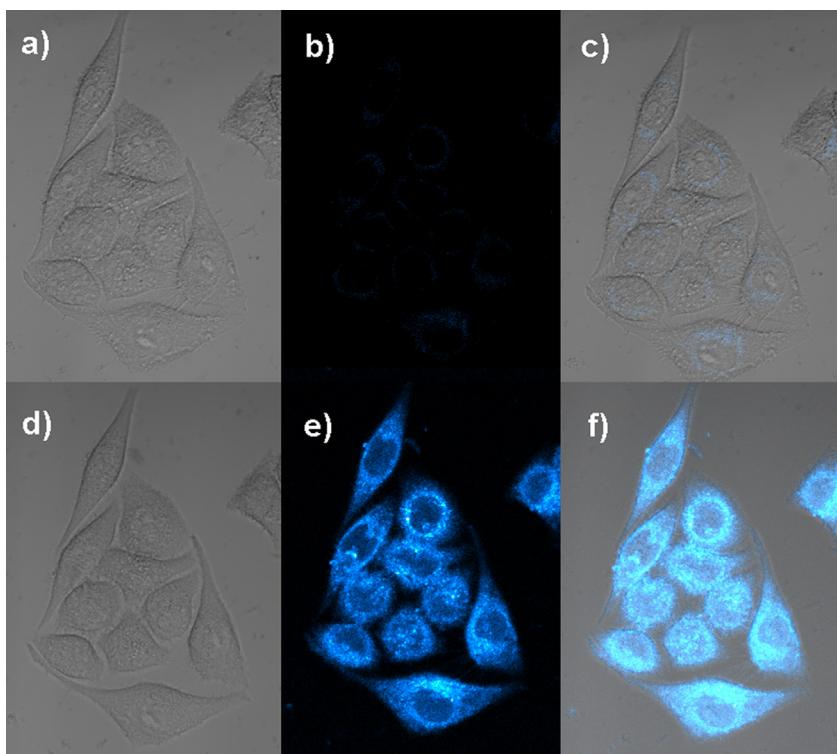

Fig. 5. Fluorescence images of live HeLa cells. From left to right are bright field images, fluorescence images and overlay images. Top (a–c): cells were incubated with **1** ($10 \mu\text{mol/L}$) for 20 min and washed with TBS twice. Bottom (d–f): cells were incubated with **1**, and then with Zn^{2+} ($10 \mu\text{mol/L}$) and pyrithione ($10 \mu\text{mol/L}$) for 20 min and washed with TBS twice. Emission was collected at 430–490 nm upon excitation at 405 nm.

7.0, while in acidic solutions the pyridine group may be protonated so that the Zn^{2+} binding should be weakened. The fluorescence of **1**- Zn^{2+} was decreased at $\text{pH} > 7$ due to the competition between OH^- and **1** in binding to Zn^{2+} . In order to obtain a higher signal-to-noise ratio and for compatibility with biological samples, pH 7.0 was employed for Zn^{2+} detection.

3.4. Analytical performance of **1** toward Zn^{2+}

According to the optimized conditions in 99% water/DMSO (v/v) at pH 7.0 buffered by 10 mmol/L Tris-HCl, the calibration curves for the determination of Zn^{2+} by **1** were constructed (Fig. 4). The linear range was at least 0.10 – $1.00 \mu\text{mol/L}$ with a correlation coefficient of $R^2 = 0.999$ ($n = 3$). The detection limit, based on the definition by IUPAC ($C_{DL} = 3S_b/m$) from 10 blank solutions, was found to be 30 nmol/L . The relative standard deviation (R.S.D.) for three repeated measurements of $0.50 \mu\text{mol/L}$ Zn^{2+} was 1.6% . The content of Zn^{2+} in tap water sample and a synthesized water sample were analyzed by the proposed method under optimized condition. The results were summarized in Table S2, which showed satisfactory recovery and R.S.D. values for all of the samples.

3.5. Fluorescence imaging of intercellular Zn^{2+}

The application of **1** for fluorescence imaging of Zn^{2+} in live HeLa cells was investigated. As observed by a laser scanning confocal microscopy, HeLa cells incubated with $10 \mu\text{mol/L}$ **1** for 20 min at 37°C gave no intracellular fluorescence. Then, the cells were supplemented with $10 \mu\text{mol/L}$ Zn^{2+} and $10 \mu\text{mol/L}$ pyrithione, which is a zinc selective ionophore [10,32], for 20 min at 37°C and washed with TBS twice, a significant fluorescence increase from the intracellular area was observed (Fig. 5). These results suggested that **1** may be used as an effective chemosensor for the imaging of Zn^{2+} in living cells.

4. Conclusions

In summary, we have developed a series of salicylaldehyde-2-pyridinehydrazone derivatives as fluorescent chemosensor for Zn^{2+} with facile synthesis. With a good selectivity to Zn^{2+} over other physiological relevant metal ions, **1** showed a “turn-on” fluorescence response toward Zn^{2+} in water at neutral pH. Moreover, confocal fluorescence microscopy experiments suggested that **1** may be used as a chemosensor for monitoring Zn^{2+} within biological samples.
