

Trends in baseline characteristics and outcomes of Medicare beneficiaries who underwent PCI from 1/2000-11/2012

	Overall	2000	2002	2004	2006	2008	2010	2012
number	3387976	246528	293391	332988	318622	243418	204409	161667
median age(years)	75	75	75	75	75	75	75	75
female (%)	42.1	43.5	43.1	42.5	41.8	41.5	41	40.4
white (%)	90	91.5	90.9	90.4	89.9	89.5	88.6	88.1
HTN (%)	65.6	58.4	61.7	63.5	62.2	65.2	74.3	80.1
DM (%)	29.9	26	27.3	28.2	28.1	29	35.5	40.2
PVD (%)	4.9	4.3	4.7	4.5	4.7	4.7	5.2	6.6
Stroke/TIA (%)	4.2	4.4	4.2	3.9	3.7	4	4.7	5.6
HF (%)	23.4	22.3	22.3	22.4	22.6	21.3	26.2	29.9
renal failure (%)	10	3.6	4.5	5.4	12.2	10.5	17.6	24.5
acute MI (%)	29.9	26.9	27.5	26.1	25.9	30.8	37.6	45.8
elective (%)	43.1	39.1	41.5	45.3	47.4	40.1	40.2	47
post-procedure LOS (days)	2	2	2	2	2	2	2	3
hospital mortality (%)	2.1	2.1	2	1.8	1.8	2.1	2.4	3.1
30 day mortality (%)	3.1	3	2.8	2.6	2.7	3.2	3.7	4.6

CONCLUSIONS Patients presenting for PCI are increasingly characterized by higher comorbidity burden and higher incidence of acute MI. Hospital mortality increased significantly over time, especially for patients presenting electively. Following adjustment for worsening baseline characteristics over time, adjusted hospital mortality was 42% higher in 2012 compared to 2000, OR 1.42 (95% CI 1.36-1.48).

BACKGROUND We aimed to evaluate the angiographic and long-term clinical outcomes after treatment for left main coronary artery disease (LMCAD) with bare-metal stents (BMS), first-generation, and second-generation drug-eluting stents (G1-DES and G2-DES).

METHODS The Left Main Coronary Stenting Registry in Japan is a multicenter registry enrolling 1800 consecutive patients with LMCAD treated with stent implantation between 2004 and 2012: 355 patients with BMS, 875 with G1-DES, and 570 with G2-DES. The clinical endpoints assessed included all-cause death, cardiac death, sudden death, definite or probable stent thrombosis, and target-lesion revascularization (TLR). We distinguished in-hospital death from long-term clinical outcomes. The 6-year cumulative rates of adverse events were estimated by Kaplan-Meier methods with p values from log-rank tests. The angiographic endpoint was defined as in-stent restenosis within one year after procedure. In addition to restenosis at stent-implanted site, restenosis at bifurcation site was defined as a percent diameter >50% within 5 mm from the stent-implanted bifurcation lesion in both main and side branches.

RESULTS The median follow-up duration was 3.9 years (the first and third quarters, 2.2 and 5.9 years). Among patients with BMS, G1-DES, and G2-DES, there were no significant differences in the cumulative 6-year incidences of all-cause death (24.8% vs. 23.0% vs. 23.8%, p=0.48), cardiac death (8.3% vs. 10.2% vs. 5.4%, p=0.65), sudden death (2.4% vs. 3.7% vs. 2.0%, p=0.95), and definite or probable stent thrombosis (1.6% vs. 0.8% vs. 2.1%, p=0.11),

whereas patients with BMS had a significantly higher cumulative rate of TLR than those with G1- and G2-DES (26.6% vs. 15.4% vs. 10.4%, p<0.001). In this study sample, 1394 patients (77.4%) underwent follow-up angiography within one year after the initial procedure. The in-stent restenosis rate was significantly higher in patients with BMS than in those with 1st and 2nd DES (27.2% vs. 11.7% vs. 5.7%, p<0.001). The restenosis rate in the proximal left main stem showed no significant difference between patients with G1- and G2-DES (3.2% vs. 2.4%, p=0.48), whereas the main and side bifurcation restenosis rates were significantly higher in patients with G1-DES than in those with G2-DES (5.0% vs. 2.4%, p=0.04 and 5.3% vs. 1.3%, p<0.001).

CONCLUSIONS DES for LMCAD appeared to be associated with more favorable outcomes of TLR than BMS. Although G2-DES improved the in-stent restenosis rate compared with G1-DES, especially in both main and side bifurcation lesions, long-term clinical outcomes after stent implantation for LMCAD were comparable between G1- and G2-DES.

BACKGROUND Peripheral vascular interventions with drug eluting balloons (DEB) have been demonstrated to be superior to balloon angioplasty (BA) in short-term follow up (6 months). Long-term outcomes remain uncertain and we therefore assessed the long-term outcomes at or beyond 12 months in this meta-analysis.

METHODS PubMed, EBSCO and Ovid databases were searched to identify randomized controlled trials (RCT) comparing drug-eluting balloons with balloon angioplasty for the management of femoropopliteal and or infrapopliteal vascular disease. Outcomes of target lesion revascularization (TLR), patency rates, death and amputations were compared between the two groups using random effects models and risk ratio (RR) with 95% confidence intervals were calculated.

RESULTS A total of 9 RCT's were identified and included 1058 patients. Of these, 585 and 473 patients were randomized to DEB and BA groups, respectively. The risk of TLR was significantly lower in the DEB group at 12 months (RR 0.34, 95% CI 0.22 - 0.53, p<0.01) and 24 months (RR 0.37, 95% CI 0.16 - 0.84, p=0.02) compared to BA group. The patency rates were higher with the use of DEB (RR 1.64, 95% CI 1.44 - 1.86, p<0.01). The risk of death was similar in both the groups (RR 1.23, 95% CI 0.65 - 2.34, p=0.52). There was a favorable trend towards decrease in amputations with the use of DEB, however this finding was not statistically significant (RR 0.64, 95% CI 0.17 - 2.53, p=0.54). Heterogeneity was very low among the included studies as assessed by Cochrane Q statistic (I²=25%). Publication bias was assessed by means of funnel plot and this was deemed to be minimal.
