Abstract

Understanding the hydraulics around injection and production wells in unconfined aquifers associated with rainwater and reclaimed water aquifer storage schemes is an issue of increasing importance. Much work has been done previously to understand the mathematics associated with Darcy's law in this context. However, groundwater flow velocities around injection and production wells are likely to be sufficiently large such as to induce significant non-Darcy effects. This article presents a mathematical analysis to look at Forchheimer's equation in the context of water injection and water production in unconfined aquifers. Three different approximate solutions are derived using quasi-steady-state assumptions and the method of matched asymptotic expansion. The resulting approximate solutions are shown to be accurate for a wide range of practical scenarios by comparison with a finite difference solution to the full problem of concern. The approximate solutions have led to an improved understanding of the flow dynamics of concern. They can also be used as verification tools for future numerical models in this context.

Keywords: Forchheimer equation, Unconfined aquifers, Non-Darcy flow

20 1. Introduction

21 With the ever increasing significance of climate change induced rainfall variability combined
22 with increasing urban populations, understanding the well hydraulics associated with managed
23 aquifer recharge schemes continues to be an important research topic for water managers around
24 the world (Bouwer, 2002; Dillon, 2005; Sheng, 2005; Pliakas et al., 2005). Such schemes typically
25 involve storing rainwater in aquifers during abundant periods and extracting it when droughts
26 occur (Donovan et al., 2002; Khan, 2008). In some cases, reclaimed wastewater is injected into
27 aquifers with a view that aquifer storage can provide additional treatment (Bouwer, 2002; Dillon,
28 2005) such that, after sufficient time, the water satisfies local drinking water quality standards
29 (Rygaard et al., 2011).

30 Appropriate hydraulic models can serve to estimate the conditions under which overflow in-
31 duced by well recharge might occur (Sheng, 2005), to estimate the recovery potential of stored
32 water, to estimate resident times in aquifers for bioremediation capacity, to forecast negative im-
33 pacts of recharge on building foundations, pipelines and deep rooted vegetation and to compute
34 energy requirements for aquifer recharge recovery schemes.

35 In most studies of well hydraulics, it is assumed that the flow behavior can be described by
36 Darcy's law. By further taking into account the continuity equation, the water table evolution in
37 unconfined aquifers can be described by a single non-linear partial differential equation (PDE), the
38 Boussinesq equation (e.g. Bear, 1979).

39 Existing analytical solutions of the non-linear Boussinesq equation for radial, transient, uncon-
40 fined flow induced by water injection to an unconfined aquifer are limited to Darcy-flow conditions

41 and to initially dry aquifer conditions (Yeh and Chang, 2013). Babu and van Genuchten (1980)
42 used similarity transforms to transform the Boussinesq equation to an ordinary differential equa-
43 tion (ODE) and then provided an approximate solution using a perturbation expansion. A similar
44 ODE was derived using similarity transforms by Barenblatt et al. (1990), to which Li et al. (2005)
45 provided asymptotic solutions for both small and large values of the similarity variable. Li et al.
46 (2005) combined these expansions to yield an approximate solution valid for all values of the
47 similarity variable, which they verified by comparison to equivalent numerical results.

48 Analytical solutions of the linearised radial or two-dimensional Boussinesq equation for tran-
49 sient flow induced by water injection to an unconfined aquifer are more abundant (Hunt, 1971;
50 Marino and Yeh, 1972; Rai and Singh, 1995; Manglik et al., 1997; Teloglou et al., 2008). Both the
51 cases that water is introduced to an aquifer by an injection well (Marino and Yeh, 1972), or by a
52 recharge basin (Rai et al., 1998) are examined. A linearization of the Boussinesq equation either in
53 terms of h , (Rai and Singh, 1995) or in h^2 , (where h is the water table elevation relative to the base
54 of the aquifer), is generally adopted. The resulting linear PDE is solved using the Laplace trans-
55 form method, the finite Hankel transform approach and/or the eigenvalue-eigenfunction method
56 (Marino and Yeh, 1972; Teloglou et al., 2008; Rai et al., 1998). Nevertheless the application
57 range of the solutions above is limited to the case that the perturbation of the water table elevation
58 induced by the water recharge is small.

59 Due to high velocities, inertial non-Darcy flow conditions may occur in the well vicinity (Math-
60 ias and Todman, 2010; Moutsopoulos et al., 2009). Non-Darcy effects cause additional head losses,
61 so that for the injection well problem, the rise of the head at the near well field would be higher
62 than predicted by Darcy's law. The potential engineering implications of these non-Darcy effects

63 are increased danger of overflow for water injection and increased energy consumption for water
64 production.

65 Semi-analytical solutions for one-dimensional (non-radial) transient Forcheimer flow in un-
66 confined aquifers have previously been developed by Bordier and Zimmer (2000) and Moutsopou-
67 los (2007, 2009). A semi-analytical solution for one-dimensional steady state radial flow in uncon-
68 fined aquifers has previously been presented by Terzidis (2003). However, to better understand the
69 role of non-Darcy effects during water injection in unconfined aquifers, we present a series of new
70 approximate analytical solutions to explore one-dimensional transient radial Forchheimer flow in
71 unconfined aquifers.

72 The outline of this article is as follows: The governing equations for transient one-dimensional
73 radial Forchheimer flow in a homogenous and isotropic unconfined aquifer are presented. The
74 equations are normalized using an appropriate set of dimensionless transformations. Following
75 the ideas of Bordier and Zimmer (2000) and Sen (1986), two different approximate solutions for
76 Darcian flow and strongly non-Darcian flow are derived for initial saturated zones of arbitrary
77 thickness by invoking a quasi-steady-state assumption. Following Mathias et al. (2008), an ap-
78 proximate solution for non-Darcy flow in an aquifer with a moderately deep initial saturated zone
79 is derived using the method of matched asymptotic expansion. The performance of the new ap-
80 proximate solutions are verified by comparison to a finite difference solution of the full problem.

81 **2. Governing equations**

82 Consider the injection/production of water into/from a homogenous and isotropic unconfined
83 aquifer. Considering the so-called Dupuit assumption (that vertical flow is negligible) (Bear,

84 1979), an appropriate one-dimensional mass conservation equation can be written as

$$S_y \frac{\partial h}{\partial t} = -\frac{1}{r} \frac{\partial(rhq)}{\partial r} \quad (1)$$

85 where (Forchheimer, 1901)

$$q + \frac{bK}{g} |q|q = -K \frac{\partial h}{\partial r} \quad (2)$$

86 and S_y [-] is the specific yield, h [L] is the water table elevation above a horizontal impermeable
 87 formation, t [T] is time, r [L] is radial distance from an injection well, b [L⁻¹] is the Forchheimer
 88 coefficient, K [LT⁻¹] is the hydraulic conductivity of the unconfined aquifer and g [LT⁻²] is the
 89 gravitational acceleration constant.

90 The relevant initial and boundary conditions can be stated as:

$$\begin{aligned} h &= h_i, & r > 0, & t = 0 \\ 2\pi rhq &= \gamma Q_0, & r \rightarrow 0, & t > 0 \\ q &= 0, & r \rightarrow \infty, & t > 0 \end{aligned} \quad (3)$$

91 where h_i [L] is a uniform initial water table elevation, Q_0 [L³T⁻¹] is a positive valued flow rate
 92 associated with a production well or injection well located at $r = 0$ with $\gamma = 1$ for an injection
 93 well and $\gamma = -1$ for a production well.

94 Note that Eq. (2) can be rearranged to the form (Mathias et al., 2014; Mathias and Wen, 2015))

$$q = -FK \frac{\partial h}{\partial r} \quad (4)$$

95 where

$$F = 2 \left[1 + \left(1 + \frac{4bK^2}{g} \left| \frac{\partial h}{\partial r} \right| \right)^{1/2} \right]^{-1} \quad (5)$$

96 3. Dimensionless transformation

97 It is helpful at this stage to apply the following dimensionless transformations:

$$t_D = \frac{Kt}{S_y H}, \quad r_D = \frac{r}{H}, \quad h_D = \frac{h - h_i}{H}, \quad q_D = \frac{q}{K}, \quad \epsilon = \frac{h_i}{H}, \quad \beta = \frac{bK^2}{g} \quad (6)$$

98 where

$$H = \left(\frac{Q_0}{2\pi K} \right)^{1/2} \quad (7)$$

99 such that the above problem reduces to

$$\frac{\partial h_D}{\partial t_D} = -\frac{1}{r_D} \frac{\partial}{\partial r_D} [r_D (h_D + \epsilon) q_D] \quad (8)$$

$$q_D = -F \frac{\partial h_D}{\partial r_D} \quad (9)$$

$$F = 2 \left[1 + \left(1 + 4\beta \left| \frac{\partial h_D}{\partial r_D} \right| \right)^{1/2} \right]^{-1} \quad (10)$$

$$\begin{aligned}
h_D &= 0, & r_D &> 0, & t_D &= 0 \\
r_D (h_D + \epsilon) q_D &= \gamma, & r_D &\rightarrow 0, & t_D &> 0 \\
q_D &= 0, & r_D &\rightarrow \infty, & t_D &> 0
\end{aligned} \tag{11}$$

100 Note that it is also possible to state that

$$q_D + \beta |q_D| q_D = -\frac{\partial h_D}{\partial r_D} \tag{12}$$

101 4. Analytical solution for large ϵ and zero β

102 The case of very large ϵ corresponds to the case of very large values of the initial water table
103 elevation or very small values of the flow-rate, such that either the raise in water table elevation in-
104 duced by water injection or the drawdown induced by water extraction can be assumed negligible.
105 In this way, the cross-sectional area, through which groundwater flow takes place, can be assumed
106 uniform and constant, such that flow processes can be described by the same equations ordinarily
107 used to describe confined aquifers. The case of zero β corresponds to a problem for which the
108 inertial effects are negligible such that the Forchheimer equation reduces to Darcy's law.

109 For very large ϵ and zero β , the problem reduces to

$$\frac{\partial h_D}{\partial t_D} = -\frac{\epsilon}{r_D} \frac{\partial (r_D q_D)}{\partial r_D} \tag{13}$$

$$\begin{aligned}
h_D &= 0, & r_D &> 0, & t_D &= 0 \\
\epsilon r_D q_D &= \gamma, & r_D &\rightarrow 0, & t_D &> 0 \\
q_D &= 0, & r_D &\rightarrow \infty, & t_D &> 0
\end{aligned} \tag{14}$$

$$q_D = -\frac{\partial h_D}{\partial r_D} \tag{15}$$

110 which has the analytical solution (Theis, 1935)

$$h_D = \frac{\gamma}{2\epsilon} E_1 \left(\frac{r_D^2}{4\epsilon t_D} \right) \tag{16}$$

111 where E_1 denotes the exponential integral function.

112 Eq. (16) above is often referred to as the Theis solution and is frequently applied to describe
113 drawdown around a fully penetrating production well situated within a homogenous and isotropic
114 confined aquifer of infinite lateral extent (Bear, 1979).

115 5. Quasi-steady state solutions

116 In the following subsections, a series of quasi-steady-state solutions are obtained using a vol-
117 ume balance approach previously applied to obtain an approximate solution for transient non-
118 Darcy radial flow in a confined aquifer by Sen (1986). After some time has passed, the system can
119 be expected to behave as in a quasi-steady-state (Bordier and Zimmer, 2000) such that

$$q_D = \begin{cases} \frac{\gamma}{(h_D + \epsilon)r_D}, & 0 \leq r_D < r_{eD} \\ 0, & r_D \geq r_{eD} \end{cases} \quad (17)$$

120 where r_{eD} is a dimensionless radius of influence, which varies with time, t_D . From mass conserva-
 121 tion considerations it can be shown that

$$t_D = \gamma \int_0^{r_{eD}} r_D h_D dr_D \quad (18)$$

122 Noting that

$$h_D = 0, \quad r_D = r_{eD} \quad (19)$$

123 application of integration by parts to Eq. (18) leads to

$$t_D = \frac{\gamma}{2} \int_0^{h_{0D}} r_D^2 dh_D \quad (20)$$

124 where

$$h_{0D} = \begin{cases} \infty, & \gamma = 1 \\ -\epsilon, & \gamma = -1 \end{cases} \quad (21)$$

125 because it is not physically possible for $h_D < -\epsilon$.

126 *5.1. Approximate solution for zero β*

127 When $\beta = 0$, Eq. (15) can be substituted into Eq. (17) to yield

$$\frac{\partial h_D}{\partial r_D} = -\frac{\gamma}{(h_D + \epsilon)r_D} \quad (22)$$

128 Separating variables, integrating both sides of Eq. (22) with respect to r_D and finding the
129 integration constant by imposing Eq. (19) then leads to

$$\frac{h_D^2}{2} + \epsilon h_D = -\gamma \ln\left(\frac{r_D}{r_{eD}}\right) \quad (23)$$

130 which can be rearranged to obtain

$$h_D = 2\gamma \ln\left(\frac{r_{eD}}{r_D}\right) \left\{ \epsilon + \left[\epsilon^2 + 2\gamma \ln\left(\frac{r_{eD}}{r_D}\right) \right]^{1/2} \right\}^{-1} \quad (24)$$

131 and

$$r_D^2 = r_{eD}^2 \exp\left[-\frac{(h_D^2 + 2\epsilon h_D)}{\gamma}\right] \quad (25)$$

132 A relationship between r_{eD} and t_D can be obtained by substituting Eq. (25) into Eq. (20) to
133 obtain (Wolfram Research, Inc., 2015)

$$\frac{t_D}{r_{eD}^2} = \frac{\pi^{1/2}\gamma^{3/2}e^{\epsilon^2/\gamma}}{4} \left[\operatorname{erf}\left(\frac{h_D + \epsilon}{\gamma^{1/2}}\right) \right]_0^{h_{0D}} \quad (26)$$

134 where erf denotes the error function.

135 *5.1.1. Injection scenario*

136 For an injection scenario $\gamma = 1$, and recalling Eq. (21), Eq. (26) reduces to

$$r_{eD} = \left[\frac{\pi^{1/2} e^{\epsilon^2} \operatorname{erfc}(\epsilon)}{4t_D} \right]^{-1/2} \quad (27)$$

137 where erfc denotes the complementary error function.

138 A relevant expansion for $\operatorname{erfc}(x)$ includes (Wolfram Research, Inc., 2015)

$$\operatorname{erfc}(x) = \frac{e^{-x^2}}{\pi^{1/2}} \left(\frac{1}{x} - \frac{1}{2x^3} + O(x^{-5}) \right) \quad (28)$$

139 from which it follows that

$$r_{eD} = \left[\frac{1}{4t_D} \left(\frac{1}{\epsilon} + O(\epsilon^{-3}) \right) \right]^{-1/2} \quad (29)$$

140 *5.1.2. Production scenario*

141 For a production scenario $\gamma = -1$, and recalling Eq. (21), Eq. (26) reduces to

$$r_{eD} = \left[\frac{\pi^{1/2} e^{-\epsilon^2} \operatorname{erfi}(\epsilon)}{4t_D} \right]^{-1/2} \quad (30)$$

142 where erfi denotes the imaginary error function. Also note that $\operatorname{erfi}(x) = -i \operatorname{erf}(ix)$, $\operatorname{erfi}(0) = 0$ and

143 $\operatorname{erfi}(-x) = -\operatorname{erfi}(x)$.

144 Relevant expansion for $\operatorname{erfi}(x)$ includes (Wolfram Research, Inc., 2015)

$$\operatorname{erfi}(x) = -i + \frac{e^{x^2}}{\pi^{1/2}} \left[\frac{1}{x} + \frac{1}{2x^3} + O(x^{-5}) \right] \quad (31)$$

145 from which it follows that

$$r_{eD} = \left[\frac{1}{4t_D} \left(\frac{1}{\epsilon} + O(\epsilon^{-3}) \right) \right]^{-1/2} \quad (32)$$

146 *5.1.3. Correction for early-time response*

147 For large ϵ , Eq. (24) reduces to

$$h_D = \frac{1}{\epsilon} \ln \left(\frac{r_{eD}}{r_D} \right), \quad \epsilon \gg 2h_D \quad (33)$$

148 Interestingly, for large times, Eq. (16) can be written as (Cooper and Jacob, 1946)

$$h_D = \frac{1}{\epsilon} \ln \left(\frac{r_{eD} e^{-0.5772/2}}{r_D} \right) \quad (34)$$

149 where r_{eD} is found from Eq. (29).

150 Furthermore, substitution of Eq. (29) into Eq. (16) leads to

$$h_D = \frac{1}{2\epsilon} E_1 \left(\frac{r_D^2}{r_{eD}^2} \right) \quad (35)$$

151 By further consideration of Eq. (24), it therefore follows that a better approximation to the full

152 Darcian problem of concern takes the form

$$h_D = \gamma E_1 \left(\frac{r_D^2}{r_{eD}^2} \right) \left\{ \epsilon + \left[\epsilon^2 + \gamma E_1 \left(\frac{r_D^2}{r_{eD}^2} \right) \right]^{1/2} \right\}^{-1} \quad (36)$$

153 where r_{eD} is found from

$$r_{eD}^{-2} = \frac{\pi^{1/2} e^{\epsilon^2/\gamma}}{4t_D} \begin{cases} \operatorname{erfc}(\epsilon), & \gamma = 1 \\ \operatorname{erfi}(\epsilon), & \gamma = -1 \end{cases} \quad (37)$$

154 As ϵ becomes large, Eq. (36) converges exactly on to the Theis solution, given in Eq. (16), for
155 both small and large times.

156 5.2. Approximate solution for large β

157 For very large β values, Eq. (15) should be replaced with

$$\gamma\beta q_D^2 = -\frac{\partial h_D}{\partial r_D} \quad (38)$$

158 which on substitution into Eq. (17) leads to

$$\frac{\gamma\beta}{[(h_D + \epsilon)r_D]^2} = -\frac{\partial h_D}{\partial r_D} \quad (39)$$

159 which integrates to obtain

$$\frac{h_D^3}{3} + \epsilon h_D^2 + \epsilon^2 h_D = \gamma\beta \left(\frac{1}{r_D} - \frac{1}{r_{eD}} \right) \quad (40)$$

160 where again, r_{eD} is defined as the radial distance at which $h_D = 0$.

161 The only real root of Eq. (40) takes the form

$$h_D = (\epsilon^3 + F)^{1/3} - \epsilon \quad (41)$$

162 where

$$F = 3\gamma\beta \left(\frac{1}{r_D} - \frac{1}{r_{eD}} \right) \quad (42)$$

163 To better understand how Eq. (41) behaves for large ϵ , it is useful to multiply the top and
164 bottom by

$$(\epsilon^3 + F)^{2/3} + (\epsilon^3 + F)^{1/3}\epsilon + \epsilon^2 \quad (43)$$

165 which reveals that

$$h_D = \frac{F}{(\epsilon^3 + F)^{2/3} + (\epsilon^3 + F)^{1/3}\epsilon + \epsilon^2} \quad (44)$$

166 5.2.1. Zero ϵ scenario

167 When $\epsilon = 0$, Eq. (41) reduces to

$$h_D = \left[3\gamma\beta \left(\frac{1}{r_D} - \frac{1}{r_{eD}} \right) \right]^{1/3} \quad (45)$$

168 which can be rearranged to get

$$r_D^2 = \left(\frac{h_D^3}{3\gamma\beta} + \frac{1}{r_{eD}} \right)^{-2} \quad (46)$$

169 which on substitution into Eq. (20) leads to (Wolfram Research, Inc., 2015)

$$t_D = \left\{ \frac{\gamma r_{eD}^{5/3} \eta^{1/3}}{18} \left[\ln \left(\frac{(r_{eD}^{1/3} h_D + \eta^{1/3})^2}{r_{eD}^{2/3} h_D^2 - \eta^{1/3} r_{eD}^{1/3} h_D + \eta^{2/3}} \right) - 2(3^{1/2}) \arctan \left(\frac{1 - 2(r_{eD}/\eta)^{1/3} h_D}{3^{1/2}} \right) \right] + \frac{\gamma \eta r_{eD}^2 h_D}{6(r_{eD} h_D^3 + \eta)} \right\}_0^{h_{0D}} \quad (47)$$

170 where $\eta = 3\gamma\beta$.

171 Eq. (47) can be simplified substantially to obtain

$$r_{eD} = \begin{cases} \left[\frac{3^{13/2}}{\beta} \left(\frac{t_D}{2\pi} \right)^3 \right]^{1/5}, & \gamma = 1 \\ \infty, & \gamma = -1 \end{cases} \quad (48)$$

172 5.2.2. Large ϵ scenario

173 When $\epsilon \gg F$, Eq. (40) reduces to

$$h_D = \frac{\gamma\beta}{\epsilon^2} \left(\frac{1}{r_D} - \frac{1}{r_{eD}} \right) \quad (49)$$

174 which on substitution into Eq. (18) and rearranging leads to

$$r_{eD} = \frac{2\epsilon^2 t_D}{\beta} \quad (50)$$

175 5.2.3. Intermediate ϵ scenario

176 From the above sub-sections it can be seen that r_{eD} grows with t_D at different rates depending
 177 on ϵ . Eqs. (48) and (50) intersect when $t_D = t_{cD}$, where t_{cD} is a dimensionless critical time, found
 178 from

$$t_{cD} = \frac{3^{13/4}\beta^2}{16\pi^{3/2}\epsilon^5} \quad (51)$$

179 For intermediate values of ϵ , a good approximation for r_{eD} can be obtained from

$$r_{eD} = \begin{cases} \left[\frac{3^{13/2}}{\beta} \left(\frac{t_D}{2\pi} \right)^3 \right]^{1/5} & t_D < t_{cD} \\ \frac{2\epsilon^2 t_D}{\beta} & t_D \geq t_{cD} \end{cases} \quad (52)$$

180 6. Solution by matched asymptotic expansion

181 At large times, the head profile has spread out over a large distance. This can be specified by
182 writing (Roose et al., 2001)

$$t_D = \frac{\epsilon^2 \tau}{\beta^2} \quad \text{and} \quad r_D = \frac{\epsilon R}{\beta} \quad (53)$$

183 Let the outer and inner limit processes of h_D be denoted h_0 and h_0^* , respectively.

184 6.1. Solution for the outer limit process

185 The solution of the outer limit process takes the form (recall Eq. (16)) (Roose et al., 2001;
186 Mathias et al., 2008)

$$h_0 = BE_1 \left(\frac{R^2}{4\epsilon\tau} \right) \quad (54)$$

187 where B is an integration constant yet to be defined and E_1 denotes the exponential integral func-
188 tion.

189 6.2. Solution for the inner limit process

190 For the inner region near the injection well, it is better to revert back to the variable r_D such
 191 that the inner limit process is characterized by

$$\frac{\beta^2}{\epsilon^2} \frac{\partial h_0^*}{\partial \tau} = -\frac{1}{r_D} \frac{\partial}{\partial r_D} [r_D (h_0^* + \epsilon) q_0^*] \quad (55)$$

192 where

$$q_0^* + \beta |q_0^*| q_0^* = -\frac{\partial h_0^*}{\partial r_D} \quad (56)$$

193 from which it follows that

$$\frac{\partial}{\partial r_D} [r_D (h_0^* + \epsilon) q_0^*] = O\left(\frac{\beta^2}{\epsilon^2}\right) \quad (57)$$

194 Integrating Eq. (57) with respect to r_D and applying the $r_D \rightarrow 0$ boundary condition in Eq.
 195 (11) then leads to

$$q_0^* = \frac{\gamma}{(h_0^* + \epsilon) r_D} \quad (58)$$

196 which, on substitution into Eq. (56) yields

$$\frac{1}{(h_0^* + \epsilon) r_D} + \frac{\beta}{(h_0^* + \epsilon)^2 r_D^2} = -\frac{1}{\gamma} \frac{\partial h_0^*}{\partial r_D} \quad (59)$$

197 Following an approach previously adopted by Terzidis (2003) to look at steady state non-

198 Darcian radial flow in an unconfined aquifer, consider a reference point situated a dimensionless
 199 radial distance away from the origin, r_{wD} . Let h_{w0}^* be the value of h_0^* at $r_D = r_{wD}$. Substituting
 200 $u = h_0^* - h_{w0}^*/2$ into Eq. (59) leads to

$$\frac{\partial u}{\partial r_D} = -\frac{2\gamma}{(2u + h_{w0}^* + 2\epsilon)r_D} \left[1 + \frac{2\beta}{(2u + h_{w0}^* + 2\epsilon)r_D} \right] \quad (60)$$

201 Taking advantage of the expansion

$$(x + a)^{-1} = a^{-1} - xa^{-2} + x^2a^{-3} + O(a^{-4}) \quad (61)$$

202 it can be seen that

$$\frac{\partial u}{\partial r_D} = -\frac{2\gamma}{(2u + h_{w0}^* + 2\epsilon)r_D} \left[1 + \frac{2\beta}{(h_{w0}^* + 2\epsilon)r_D} \right] + O((h_{w0}^* + 2\epsilon)^{-3}) \quad (62)$$

203 Separating variables and integrating with respect to r_D yields

$$u^2 + (h_{w0}^* + 2\epsilon)u - 2G = 0 \quad (63)$$

204 where

$$G = \gamma \left[\frac{2\beta}{(h_{w0}^* + 2\epsilon)r_D} - \ln r_D \right] + C \quad (64)$$

205 The positive root of Eq. (63) is of practical interest:

$$2u = -(h_{w0}^* + 2\epsilon) + [(h_{w0}^* + 2\epsilon)^2 + 8G]^{1/2} \quad (65)$$

206 Taking advantage of the expansion

$$(x + a)^{1/2} = a^{1/2} + \frac{x}{2a^{1/2}} - \frac{x^2}{8a^{3/2}} + O(a^{-5/2}) \quad (66)$$

207 and reversing the u substitution it can be seen that

$$h_0^* = \frac{h_{w0}^*}{2} + \frac{2G}{(h_{w0}^* + 2\epsilon)} - \frac{4G^2}{(h_{w0}^* + 2\epsilon)^3} + O((h_{w0}^* + 2\epsilon)^{-5}) \quad (67)$$

208 Noting that the truncation error in Eq. (62) is $O((h_{w0}^* + 2\epsilon)^{-3})$, for consistency, the third term
209 on the right-hand-side of Eq. (67) should also be excluded such that it can be said that

$$h_0^* = D + \gamma \left[\frac{4\beta}{(h_{w0}^* + 2\epsilon)^2 r_D} - \frac{2 \ln r_D}{(h_{w0}^* + 2\epsilon)} \right] + O((h_{w0}^* + 2\epsilon)^{-3}) \quad (68)$$

210 where D is a constant found from

$$D = \frac{h_{w0}^*}{2} + \frac{2C}{(h_{w0}^* + 2\epsilon)} \quad (69)$$

211 *6.3. Matching of inner and outer limit processes*

212 The constants B and D are determined by matching the inner and outer limit processes, i.e.

$$\lim_{r_D \rightarrow \infty} h_0^* = \lim_{R \rightarrow 0} h_0 \quad (70)$$

213 Exploiting the asymptotic expansion of the E_1 function for small R , Eq. (54) can be written in
 214 the form

$$h_0 = -B \left[0.5772 + 2 \ln r_D + \ln \left(\frac{\beta^2}{4\epsilon^3 \tau} \right) \right] + O \left(\left(\frac{\beta}{\epsilon} \right)^2 \right) \quad (71)$$

215 Therefore, by comparing Eqs. (68) and (71), it can be seen that

$$B = \frac{\gamma}{h_{w0}^* + 2\epsilon} \quad (72)$$

$$D = -\frac{\gamma}{(h_{w0}^* + 2\epsilon)} \left[0.5772 + \ln \left(\frac{\beta^2}{4\epsilon^3 \tau} \right) \right] + O \left(\left(\frac{\beta}{\epsilon} \right)^2 \right) \quad (73)$$

216 Similar to Mathias et al. (2008), adding the inner and outer limits and subtracting out of their
 217 sum the term that is common to both expressions in the overlap region then yields the composite
 218 solution

$$h_D = \frac{\gamma}{(h_{wD} + 2\epsilon)} E_1 \left(\frac{r_D^2}{4\epsilon t_D} \right) + \frac{4\gamma\beta}{(h_{wD} + 2\epsilon)^2 r_D} + O \left(\left(\frac{\beta}{\epsilon} \right)^2 \right) \quad (74)$$

219 where $h_{wD} = h_D(r_D = r_{wD})$.

220 6.4. Determining h_{wD}

221 The h_{wD} term can be obtained by finding the real root of the cubic equation

$$(h_{wD} + 2\epsilon)^3 - 2\epsilon(h_{wD} + 2\epsilon)^2 - \gamma E_1 \left(\frac{r_{wD}^2}{4\epsilon t_D} \right) (h_{wD} + 2\epsilon) - \frac{4\gamma\beta}{r_D} = 0 \quad (75)$$

222 which takes the form (Wolfram Research, Inc., 2015)

$$h_{wD} = \left[(T_1^2 - T_2^3)^{1/2} + T_1 \right]^{1/3} + T_2 \left[(T_1^2 - T_2^3)^{1/2} + T_1 \right]^{-1/3} - \frac{4\epsilon}{3} \quad (76)$$

223 where

$$T_1 = \frac{8\epsilon^3}{27} + \frac{\gamma\epsilon}{3} E_1 \left(\frac{r_{wD}^2}{r_{eD}^2} \right) + \frac{2\gamma\beta}{r_{wD}} \quad (77)$$

$$T_2 = \frac{4\epsilon^2}{9} + \frac{\gamma}{3} E_1 \left(\frac{r_{wD}^2}{r_{eD}^2} \right) \quad (78)$$

$$r_{eD} = (4\epsilon t_D)^{1/2} \quad (79)$$

226 Furthermore, it can be understood that a better approximation for h_D is obtained from

$$h_D = h_{wD}(r_{wD} = r_D) \quad (80)$$

227 and the approximation becomes identical to Eq. (36) when $\epsilon = 0$ and $\beta = 0$ if r_{eD} is calculated
228 from Eq. (37) instead. Readers may benefit from the identity

$$i^\nu + i^{-\nu} = 2 \cos\left(\frac{\nu\pi}{2}\right) \quad (81)$$

229 when verifying this for themselves.

230 7. Comparison with a finite difference solution

231 The study reported in this article has led to the development of three different approximate
232 solutions for production and injection wells in unconfined aquifers. The first approximate solution,
233 Eqs. (36) to (37), reported in section 5.1, is hereafter referred to as the zero β quasi-steady-state
234 (QSS) solution. The second approximate solution, Eqs. (44), (42), (51) and (52), reported in
235 section 5.2, is hereafter referred to as the large β QSS solution. The third approximate solution,
236 Eq. (80), Eqs. (76) to (78) and Eq. (37), reported in section 6.0, is hereafter referred to as the
237 matched asymptotic expansion solution.

238 To demonstrate the accuracy of the approximate solutions described above, results from the
239 approximate solutions are compared to equivalent results from a finite difference solution for the
240 full problem described in section 3.

241 The finite difference solution is obtained in exactly the same way as previously presented
242 by Mathias et al. (2008) but with the addition of the $(h_D + \epsilon)$ factor on the q_D values shown in
243 Eq. (8), specifically associated with unconfined aquifers. To summarize, the partial differential
244 equation in section 3 is discretised in space using finite differences. The resulting set of non-linear
245 ordinary differential equations (ODE) with respect to time are then integrated collectively using
246 MATLAB's stiff ODE solver, ODE15s. The dimensionless radial distance, r_D , is discretised into
247 100 logarithmically spaced points, with the space steps ranging across four orders of magnitude,
248 with the smallest space steps around the injection/production well. The $r_D \rightarrow 0$ and $r_D \rightarrow \infty$
249 boundary conditions are approximated by instead applying the associated boundary conditions at
250 $r_D = 0.1$ and $r_D = 1000$, respectively. Manual specification of a time-step is not required because

251 ODE15s adaptively chooses time-steps as the solution progresses.

252 An appropriate range of ϵ and β values to be studied were determined as follows. In a recent set
 253 of packed column experiments, Salahi et al. (2015) determined A [$L^{-1}T$] and B [$L^{-2}T^2$] coefficients
 254 for the Forchheimer equation in the form

$$Aq + Bq|q| = -\frac{\partial h}{\partial r} \quad (82)$$

255 for a wide range of rounded and crushed granular materials. By simple inspection it can be seen
 256 that $K = A^{-1}$ and $\beta = B/A^2$. From their Table 1, it can therefore be shown that Salahi et al. (2015)
 257 observed K values ranging from 0.022 ms^{-1} to 0.940 ms^{-1} and β values ranging from 1.438 to
 258 153.7.

259 Possible production and injection rates can be expected to range from 0.01 to 10.0 MI/day
 260 whereas h_i might range from 1 m to 100 m. Considering that

$$\epsilon = \left(\frac{2\pi K h_i^2}{Q_0} \right)^{1/2} \quad (83)$$

261 it therefore also follows that practical values for ϵ range from 1.1 to 23,000.

262 Fig. 1 shows plots of dimensionless pressure against dimensionless distance for a range of
 263 dimensionless times for the special case when $\beta = 0$ for an injection scenario (i.e., $\gamma = 1$). The
 264 first thing to note is that the matched asymptotic expansion solution and the zero β QSS solution
 265 produce identical results for all ϵ . The numerical model also produces almost identical results
 266 for $\epsilon \geq 1$. When $\epsilon = 0$ the finite difference model has less hydraulic head dispersion around the
 267 radius of influence (i.e., where h_D approaches zero). It is also interesting to see how hydraulic

268 head distance profiles deviate from a linear-log relationship, normally associated with the Theis
 269 solution, when $\epsilon < 10$.

270 Fig. 2 shows plots of dimensionless pressure against dimensionless distance for a range of
 271 dimensionless times for the case when $\beta = 100$ again for an injection scenario (i.e., $\gamma = 1$). The
 272 close correspondence between the large β QSS solution for $\epsilon \leq 1$ helps confirm that the finite dif-
 273 ference solution is performing in an accurate fashion for these scenarios. The divergence between
 274 the finite difference solution and the QSS solution for larger values of ϵ comes about because the
 275 Darcian component (which is ignored in the large β QSS solution) becomes more important when
 276 ϵ is larger. The matched asymptotic expansion solution is less effective at describing these scenar-
 277 ios except for when $\epsilon \geq 100$ and $t_D \geq 100$ when $\epsilon = 10$. This discrepancy is consistent with the
 278 order of accuracy assumed when deriving the matched asymptotic expansion solution. Further-
 279 more, it shows that the non-Darcy component of the Forchheimer equation is more important for
 280 small ϵ values (i.e., aquifers with a stronger unconfined, as opposed to confined, response).

281 Fig. 3 shows plots of dimensionless pressure against dimensionless distance for a range of
 282 dimensionless times for a production scenario (i.e., $\gamma = -1$) when $\beta = 0$ and $\beta = 1$. Note that it
 283 is not possible to solve this problem for $\epsilon = 0$ because this would imply that there is no water to
 284 produce. Figs. 3 a) and b) show production cases for when $\beta = 0$. Here it can be seen that there is
 285 excellent correspondence between the finite difference solution, the matched asymptotic expansion
 286 solution and the zero β QSS solution. Note that the solution for $\epsilon = 3$ was only simulated up to
 287 $t_D = 10$ because shortly after that the well dries out.

288 Figs. 3 c) and d) show results for water production with the Forchheimer equation (with $\beta = 1$).
 289 It is difficult to look at production scenarios with β much greater than one in conjunction with

290 moderate values of ϵ (i.e., $\epsilon \leq 10$), because the production well dries out too fast. Consequently
291 the large β QSS solution is not useful in this context. Furthermore, it can be understood that it
292 is difficult to study the significance of Forchheimer flow under strongly unconfined conditions for
293 the production scenario, because the Dupuit assumption quickly becomes invalid in the region of
294 interest. Nevertheless, it can be seen that the matched asymptotic expansion solution is capable of
295 accurately predicting the results from the finite difference solution for these scenarios.

296 By comparing Figs. 3 b) (where $\epsilon = 10$ and $\beta = 0$) to Fig. 3 d) (where $\epsilon = 10$ and $\beta = 1$), it can
297 be seen that in the latter case, where the inertial effects are non-negligible, the drawdown is more
298 significant in the well vicinity. For example for $t_D = 100$, $r_D = 0.1$ and for $\beta = 0$, $h_D = -0.64$
299 whereas for the same case but with $\beta = 1$, $h_D = -0.75$. However, for larger distances, where
300 the velocities are smaller and subsequently the inertial effects become negligible, the values of the
301 heads become identical for both values of β , because flow is Darcian in this region.

302 8. Summary and conclusions

303 This article presents a series of approximate solutions to look at Forchheimer flow around a
304 production well and injection well in an unconfined aquifer. All the presented solutions invoke the
305 Dupuit assumption that vertical flow is negligible.

306 The first approximate solution involved imposing a quasi-steady-state assumption and fixing
307 $\beta = 0$ (and hence solves for Darcy's law only). The quasi-steady-state assumption allows the
308 treatment of the hydraulic head distribution around the injection/production well as a steady state
309 profile with a radius of influence, which moves out with increasing time. The location of the radius
310 of influence is determined by forcing the integral of the hydraulic head distribution with respect

311 to distance to be consistent with the volume of water that has been injected or produced at that
312 particular point in time.

313 The second approximate solution involved imposing the same quasi-steady-state assumption
314 but with β assumed to be sufficiently large such that the Darcy component of the Forchheimer
315 equation can be ignored. This large β solution is particularly applicable for coarse grained aquifers,
316 where small water table gradients (consistent with the Dupuit assumption) often coincide with
317 fully developed turbulent conditions (consider the discussion in Moutsopoulos, 2009, Appendix
318 A).

319 The third approximate solution was obtained by solving the full problem using the method
320 of matched asymptotic expansions. The latter solution is valid for $O((\beta/\epsilon)^2)$. For large values
321 of β , large head losses occur. For small values of ϵ , either the initial water table height is small
322 or the pumping rate is large so that again the associated head losses are expected to be large.
323 Interestingly, for large values of the ratio, β/ϵ , for the production well case, the well is predicted
324 to quickly dry out such that the Dupuit assumption does not hold.

325 The three approximate solutions were compared to results from a finite difference solution
326 modified from the finite difference solution previously presented by Mathias et al. (2008) for con-
327 fined aquifers. The quasi-steady-state solutions were able to verify the finite difference solution
328 when $\beta = 0$ and when $\beta = 100$ is very large whilst $\epsilon \leq 10$. The matched asymptotic expansion
329 solution was found to accurately predict the finite difference results providing the ratio of β/ϵ is
330 suitably small. The results also illustrate that the non-Darcy component of the Forchheimer equa-
331 tion is more important for small ϵ values (i.e., aquifers with a stronger unconfined, as opposed to
332 confined, response).

333 Overall, the analysis has added further support to the idea that non-Darcy effects are likely
334 to be important around both injection wells and production wells in unconfined aquifers. The
335 matched asymptotic expansion solution derived was found to be accurate for most of the practical
336 cases studied. The solution is simple to evaluate and should be considered for future numerical
337 modeling studies as an important model verification tool.
